The K7A323630C and K7A321830C are 37,748,736-bit Synchronous Static Random Access Memory designed for high performance second level cache of Pentium and Power PC based System.

It is organized as 1M(2M) words of 36(18) bits and integrates address and control registers, a 2-bit burst address counter and added some new functions for high performance cache RAM applications; $\overline{GW}$, $\overline{BW}$, $\overline{LBO}$, $\overline{ZZ}$. Write cycles are internally self-timed and synchronous.

Full bus-width write is done by $\overline{GW}$, and each byte write is performed by the combination of $\overline{WEx}$ and $\overline{BW}$ when $\overline{GW}$ is high. And with $\overline{CS_1}$ high, $\overline{ADSP}$ is blocked to control signals.

Burst cycle can be initiated with either the address status processor (ADSP) or address status cache controller (ADSC) inputs. Subsequent burst addresses are generated internally in the system's burst sequence and are controlled by the burst address advance (ADV) input.

$\overline{\text{LBO}}$ pin is DC operated and determines burst sequence (linear or interleaved).

ZZ pin controls Power Down State and reduces Stand-by current regardless of CLK.

The K7A323630C and K7A321830C are fabricated using SAMSUNG's high performance CMOS technology and is available in a 100pin TQFP package. Multiple power and ground pins are utilized to minimize ground bounce.

FUNCTION DESCRIPTION

The K7A323630C and K7A321830C are synchronous SRAM designed to support the burst address accessing sequence of the Power PC based microprocessor. All inputs (with the exception of $\overline{OE}$, $\overline{LBO}$ and $\overline{ZZ}$) are sampled on rising clock edges. The start and duration of the burst access is controlled by $\overline{ADSC}$, $\overline{ADSP}$ and $\overline{ADV}$ and chip select pins.

The accesses are enabled with the chip select signals and output enabled signals. Wait states are inserted into the access with $\overline{ADV}$.

When $\overline{ZZ}$ is pulled high, the SRAM will enter a Power Down State. At this time, internal state of the SRAM is preserved. When $\overline{ZZ}$ returns to low, the SRAM normally operates after 2cycles of wake up time. $\overline{ZZ}$ pin is pulled down internally.

Read cycles are initiated with $\overline{ADSP}$ (regardless of $\overline{WEx}$ and $\overline{ADSC}$)using the new external address clocked into the on-chip address register whenever $\overline{ADSP}$ is sampled low, the chip selects are sampled active, and the output buffer is enabled with $\overline{OE}$. In read operation the data of cell array accessed by the current address, registered in the Data-out registers by the positive edge of $\overline{CLK}$, are carried to the Data-out buffer by the next positive edge of $\overline{CLK}$. The data, registered in the Data-out buffer, are projected to the output pins. $\overline{ADV}$ is ignored on the clock edge that samples $\overline{ADSP}$ asserted, but is sampled on the subsequent clock edges. The address increases internally for the next access of the burst when $\overline{WEx}$ are sampled High and $\overline{ADV}$ is sampled low. And $\overline{ADSP}$ is blocked to control signals by disabling $\overline{CS1}$.

All byte write is done by $\overline{GW}$ (regardless of $\overline{BW}$ and $\overline{WEx}$), and each byte write is performed by the combination of $\overline{BW}$ and $\overline{WEx}$ when $\overline{GW}$ is high.

Write cycles are performed by disabling the output buffers with $\overline{OE}$ and asserting $\overline{WEx}$. $\overline{WEx}$ are ignored on the clock edge that samples $\overline{ADSP}$ low, but are sampled on the subsequent clock edges. The output buffers are disabled when $\overline{WEx}$ are sampled Low(regardless of $\overline{OE}$). Data is clocked into the data input register when $\overline{WEx}$ sampled Low. The address increases internally to the next address of burst, if both $\overline{WEx}$ and $\overline{ADV}$ are sampled Low. Individual byte write cycles are performed by any one or more byte write enable signals($\overline{WEa}$, $\overline{WEb}$, $\overline{WEc}$ or $\overline{WEd}$) sampled low. The $\overline{WEa}$ control $\overline{DQa0} \sim \overline{DQa7}$ and $\overline{DQPa}$, $\overline{WEb}$ controls $\overline{DQb0} \sim \overline{DQb7}$ and $\overline{DQPb}$, $\overline{WEc}$ controls $\overline{DQc0} \sim \overline{DQc7}$ and $\overline{DQPC}$, and $\overline{WEd}$ control $\overline{DQd0} \sim \overline{DQd7}$ and $\overline{DQPD}$. Read or write cycle may also be initiated with $\overline{ADSC}$, instead of $\overline{ADSP}$. The differences between cycles initiated with $\overline{ADSC}$ and $\overline{ADSP}$ as are follows;

$\overline{ADSP}$ must be sampled high when $\overline{ADSC}$ is sampled low to initiate a cycle with $\overline{ADSC}$.

$\overline{WEx}$ are sampled on the same clock edge that sampled $\overline{ADSC}$ low(and $\overline{ADSP}$ high).

Addresses are generated for the burst access as shown below. The starting point of the burst sequence is provided by the external address. The burst address counter wraps around to its initial state upon completion. The burst sequence is determined by the state of the $\overline{LBO}$ pin. When this pin is Low, linear burst sequence is selected. When this pin is High, Interleaved burst sequence is selected.
