

The TDA 4001 has been designed to convert, amplify, and demodulate AM signals. In addition, the component provides a search tuning stop pulse.

Features

- Internal demodulation
- Search tuning stop signal
- Low total harmonic distortion
- Minimal IF leakage at the AF output
- 2-stage integrated low pass filter

Maximum ratings

Circuit description

The impedance converter forwards the input signal V_{iRF} to the symmetrical double balanced mixer. Subsequently the signal is converted to IF with the amplitude-controlled oscillator. An external filter forwards the IF signal to the controlled IF amplifier. The amplifier IF signal and the carrier signal will be converted to AF in the subsequent synchronous demodulator (SD). The 2-stage low pass filter forwards the available AF to the AF output. Via an additional limiter amplifier (LA), the AF uses the carrier signal to control the coincidence demodulator (CD). The output signal of the coincidence demodulator provides the stop pulse during exact tuning and sufficient field strength.
