# AHA3410C StarLite

## 25 MBYTES/SEC SIMULTANEOUS LOSSLESS DATA COMPRESSION / DECOMPRESSION COPROCESSOR IC

The high speed compression coprocessor is a single-chip CMOS VLSI device that implements a lossless compression and decompression algorithm. The algorithm exhibits an average compression ratio over 13 to 1 for bitmap image data. The device supports simultaneous compression and decompression operations at 25 MBytes/sec each.

A Non-muxed microprocessor interface connects directly to various embedded processors. An additional synchronous 32-bit port transfers data at up to 100 MBytes/sec. Scanners and print engine interfaces may optionally be connected to two 8-bit synchronous video ports for emerging multifunction laser printer and copier applications.

Software simulation and an analysis of the algorithm for printer and copier images of various complexity are available for evaluation.

NOTE: YYWWD = DATE CODE; LLLLL = LOT NUMBER

#### PERFORMANCE:

- 25 MBytes/sec compression/decompression rates
- 100 MBytes/sec burst data rate over a 32-bit data bus
- 25 MBytes/sec synchronous 8-bit video in and video out ports
- Simultaneous compression/decompression operation at full bandwidth
- Average 13 to 1 compression ratio for bitmap image data

#### FLEXIBILITY:

- Configurable I/O interface for DMA mode, Big Endian or Little Endian, and 32-bit or 16-bit bus widths
- Interfaces directly with various i960 or Motorola 68xxx family of processors
- Optional 8-bit video input and output ports
- Pass-through mode passes raw data through compression and decompression engines
- Programmable scan line length up to 2K bytes

#### SYSTEM INTERFACE:

- Single chip compression/decompression solution
- No external SRÂM required
- Four 16 x 32-bit FIFOs
- Programmable interrupts
- Output signals may be tristated to facilitate board level testing

#### OTHERS:

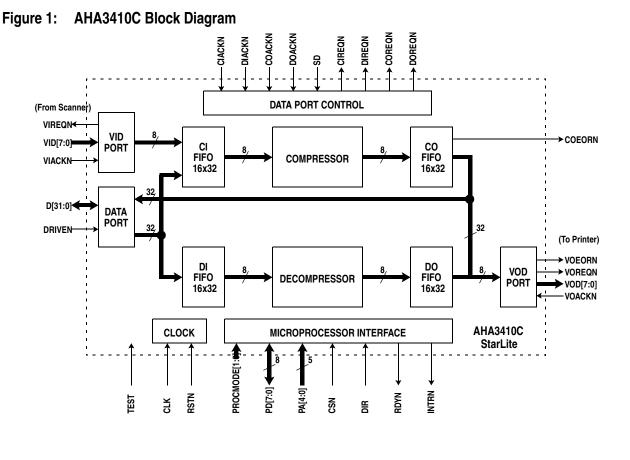

- Low power modes
- Optional counter checks errors in decompression
- Ambient temperature spec is 70°C, still air
- Software emulation program available
- 120 pin quad flat package

### APPLICATIONS

- Multifunction printers and copiers
- High performance laser printers and digital copiers

\*Request the AHA3410C Product Specification for complete details.

#### FUNCTIONAL DESCRIPTION

The coprocessor device has three external high speed synchronous data ports each capable of transferring once every 25 MHz clock. These are a 32-bit bidirectional data port, an 8-bit Video Input Data (VID) port and a Video Output Data (VOD) port. The 32-bit port is capable of transferring up to 100 MBytes/sec. The VID and VOD are capable of up to 25 MBytes/sec each.

The device accepts uncompressed data through the 32-bit data or optionally through the 8-bit VID port into its Compression In FIFO (CI FIFO). The 32-bit data port may be configured for 16-bit transfers. Compressed data is available through the 32-bit data port via the Compressed Output FIFO (CO FIFO). The sustained data rate through the compression engine is 25 MBytes/sec.

Decompression data may be simultaneously processed by the device. Decompression data is accepted through the 32-bit data port, buffered in the Decompression Input FIFO (DI FIFO), and decompressed. The output data is made available on the 32-bit data port via the Decompression Output FIFO (DO FIFO) or optionally on the 8-bit Video Output port. The decompression engine runs on the 25 MHz clock and is capable of processing an uncompressed byte every clock, i.e. 25 MBytes/sec.

The four FIFOs are organized as 16x32 each. For data transfers through the three ports, the "effective" FIFO widths differ according to their data bus widths.

Data transfer for compression or decompression is synchronous over the three data ports functioning as DMA masters. To initiate a transfer into or out of the Video ports, the device asserts VxREQN, the external device responds with VxACKN and begins to transfer data over the VID or VOD busses on each succeeding rising edge of the clock until VxREQN is deasserted. The 32-bit port relies on the FIFO Threshold settings to determine the transfer.

#### SYSTEM APPLICATION

The device is intended for memory intensive applications, such as high resolution copiers or printers. These applications require the simultaneous compression and decompression capability of the device. Copiers use this feature to feed the compressed bit maps through the decompressor to the printer engine while another process uses the compressor to input and compress scanned images. Movement for both processes is typically controlled by a DMA controller that is programmed by the local microprocessor or by programmed I/O.

#### StarLite IMAGE COMPRESSION RESULTS - 1200 x 1200 DPI

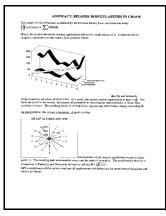

Uncompressed file size = 16 MBytes; Image dimensions =  $10200 \times 13200$  pels

It is total enough density a proportional to the angularity spanned. For a transiting mass we have $\frac{dE}{dx} = \mu m^{-2}Z_{x} \cos^{2}(kx - mt)$	the total arrange density is proportional to the any initial spaced. For a constitue over an array $\frac{dE}{dx} = \mu u r^2 Z_0 \cos^2(kx - nr)$	. In take energy density is proportional to the employed energy density is proportional to the employed energy over the law $\frac{dE}{dx} = \mu \omega^{-1} Z_{\odot} \cos^{2} (kx - \omega t)$
	The sector probability is provided to be transformed with the sector probability of the transformed to be transformed. For a transformed near the set $\frac{dE}{dx} = \mu \ln^2 Z_{\odot} \cos^2(kx - 0)t$	For even strange density is proportional to the investment of the strange density is proportional to the investment of the strange density of the strange densi
So foll showing occurs and traveling varies, the total energy density is proportional to the implicited squared. For a traveling wave we have $\frac{dE}{dx} = \mu_1 m^2 \mathbf{Z}_p \cos^2(kx - 6 \sigma)$	For both similary sums and tracellary states, we may enough decise it programmed to be employed expands. The schemistry wave vectors $\frac{dE}{dx} = \mu \cos^3 2x  x \cos^3 (kx - \omega t)$	For both standing warm and scanding varies, six could cover denote it for propositional or the anglitude squares. For a coording ware we have $\frac{dE}{d\chi}=(\mu0.5^{-2}Z_{ij}c0.s^2(k\pi-0.r))$
For both manding waves and traveling waves, the total energy density is proportional to the empirical spaced spaced. For a structling wave we have $\frac{dE}{dx} = \mu \omega ^{-2} Z_{\psi} \cos^2(kx-\omega t)$	For both charling waves and kineting waves, the batt analyst dama is properties in the implicit operation. For a tracking wave values $\frac{dE}{dx} = \mu \cos^2 Z_{\pm} \cos^2 (kx - wt)$	For both standing wires and increding reproducts the final energy density is proportional to the samples of a parameter of the second standard space. The same standard space is shown $\frac{dE}{dx} = \mu a 0.^{2} Z_{y} \cos^{2}(kx - a)r \}$
For both should prever and traveling verse, the total energy density is propertional to the tupling space. To a tuning ten to two $\frac{dE}{dx} = \mu \infty^{-1} Z_{\odot} \cos^2(kx - \omega t)$	For both models server and tracelless serves, the total energy density is proportional to the mplital space. The s tracellar wave to have $\frac{dE}{dx} = \mu \omega^{-1} Z_{\mu} \cos^2(\lambda x - \omega t)$	For both reacting values and sourced grows, the total average density is propertional in the anglithe space. For a treating way we have $\frac{dE}{dx} = \mu m^2 Z_{\mu} \cos^2(kx - mt)$
For both standing wores and torreling source. For both energy density is proportional to be amplitude against. For a traveling wave we have $\frac{dE}{dx} = \mu \omega^2 Z_0 \cos^2(kx - \Omega t)$	For the standing views and sensing meron, the total standing views in proportional total and the standard standard state of the	For both stating works and involving works, the total energy dataky is proportional to the singlified against two strengths works whole $\frac{dE}{dx} = \mu 0.3 Z_s \cos^3(kx - 0.01)$
For such similary waves and transiting waves, the solid energy density is proportional to the combined spaceol. For a transiting wave we have $\frac{dE}{dx} = \mu \omega^2 Z_y \cos^2(kx - \omega_\ell)$	For both standing varies and investing more, the initial energy density is proportional to the completion density of the standing wave we have $\frac{dE}{dx} = \mu \cos^2 Z_{ij} \cos^2 (kx - \alpha st)$	For bith stimolog reveal and leading reveal, the local energy density is popposing to the evaluation expenses. For a strateging wave are trans $\frac{dE}{dx} = \mu \cos^2 Z_{ij} \cos^2 (kx - \infty t)$
, As but strategy were not sorting work. In the control of the product to be any start to product to be any links or particle. For a travelling value we have $\frac{dE}{dx} = \mu \mathrm{star}^2 \mathbf{Z}_{\pm} \cos^2(kx - \mathrm{Gel})$	Purchased and the set of the set	Pix both strading verses and textelling verses, the total energy density is proportional to to arraffind expand. For a providing verse we have $\frac{dE}{dx} = \mu \omega^{-1} Z_{\pm} \cos^2(kx - \omega x)$
For both standing waves and traveling waves, the tool carry density is propulsed to the supplicate equand. For a taseful grave we have $\frac{dE}{dx} = \mu \omega^2 Z_{\pm} \cos^2(kx - \omega t)$	The the matrix distribution of the lattice of the second state of	For both monday scalar and consoling scalar, the local cavery density is propertiend to the spanned. For a specific scalar we have $\frac{dE}{dx}=\mu(\alpha)^2 Z_{\pm}\cos(i(x-\alpha)t)$
The both standard verses and travel ing waves, the total carry density is preparitient to the applicit source. For a covering wave we have $\frac{dE}{dx} = \mu\Omega^{-2}Z_{\pm}\cos^2(kx - 0.0)$	An initial results in the second constitute values, the initial energy density is proportioned in the analytical second $T$ is a starting wave or how and table second $T$ is a starting wave or how and $\frac{dE}{dx} = 0.05^{-2} \mathrm{Z}_{\phi} \cos^2(kx - 0.01)$	For both bialogs were not treating word, the tool energy density is proposal to the emphasization of the group density is proposalize over the density of the group density of the second density of the

#### ABOUT AHA

Comtech AHA Corporation (AHA) develops and markets superior integrated circuits, boards, and intellectual property core technology for communications systems architects worldwide. AHA has been setting the standard in Forward Error Correction and Lossless Data Compression technology for many years and provides flexible, cost-effective solutions for today's growing bandwidth and reliability challenges. Comtech AHA Corporation is a wholly owned subsidiary of Comtech Telecommuncations Corp. (NASDAQ: CMTL). For more information, visit www.aha.com.
