

Frequency Generator & Integrated Buffers for PENTIUM/Pro™

General Description

The **ICS9148-08** generates all clocks required for high speed RISC or CISC microprocessor systems such as Intel PentiumPro or Cyrix. Eight different reference frequency multiplying factors are externally selectable with smooth frequency transitions.

Features include four CPU, seven PCI and Twelve SDRAM clocks. Two reference outputs are available equal to the crystal frequency. Plus the IOAPIC output powered by VDDL1. One 48 MHz for USB, and one 24 MHz clock for Super IO. Spread Spectrum built in $\pm 1.5\%$ modulation to reduce the EMI. Serial programming I²C interface allows changing functions, stop clock programing and Frequency selection. Rise time adjustment for VDD at 3.3V or 2.5V CPU. Additionally, the device meets the Pentium power-up stabilization, which requires that CPU and PCI clocks be stable within 2ms after power-up. It is not recommended to use I/O dual function pin for the slots (ISA, PCI, CPU, DIMM). The add on card might have a pull up or pull down.

High drive PCICLK and SDRAM outputs typically provide greater than 1 V/ns slew rate into 30pF loads. CPUCLK outputs typically provide better than 1V/ns slew rate into 20pF loads while maintaining 50 $\pm$ 5% duty cycle. The REF and 24 and 48 MHz clock outputs typically provide better than 0.5V/ns slew rates.

Features

- 3.3V outputs: SDRAM, PCI, REF, 48/24 MHz
- 2.5V or 3.3V outputs; CPU, IOAPIC
- 20 ohm CPU clock output impedance
- 20 ohm PCI clock output impedance
- Skew from CPU (earlier) to PCI clock - 1 to 4 ns, center 2.6 ns.
- No external load cap for C_L=18pF crystals
- ± 250 ps CPU, PCI clock skew
- 400ps (cycle to cycle) CPU jitter
- Smooth frequency switch, with selections from 50 to 83.3 MHz CPU.
- I²C interface for programming
- 2ms power up clock stable time
- Clock duty cycle 45-55%.
- 48 pin 300 mil SSOP package
- 3.3V operation, 5V tolerant input.

General I²C serial interface information

- A. For the clock generator to be addressed by an I²C controller, the following address must be sent as a start sequence, with an acknowledge bit between each byte.

Clock Generator Address (7 bits)	ACK	+ 8 bits dummy command code	ACK	+ 8 bits dummy Byte count	ACK
A(6:0) & R/W#					
D2(H)					

Then Byte 0, 1, 2, etc in sequence until STOP.

- B. The clock generator is a slave/receiver I²C component. It can "read back "(in Philips I²C protocol) the data stored in the latches for verification. (set R/W# to 1 above). There is no BYTE count supported, so it does not meet the Intel SMB PIIX4 protocol.

Clock Generator Address (7 bits)	ACK	Byte 0	ACK	Byte 1	ACK
A(6:0) & R/W#					
D3(H)					

Byte 0, 1, 2, etc in sequence until STOP.

- C. The data transfer rate supported by this clock generator is 100K bits/sec (standard mode)
- D. The input is operating at 3.3V logic levels.
- E. The data byte format is 8 bit bytes.
- F. To simplify the clock generator I²C interface, the protocol is set to use only block writes from the controller. The bytes must be accessed in sequential order from lowest to highest byte with the ability to stop after any complete byte has been transferred. The Command code and Byte count shown above must be sent, but the data is ignored for those two bytes. The data is loaded until a Stop sequence is issued.
- G. In the power down mode (PWR_DWN# Low), the SDATA and SCLK pins are tristated and the internal data latches maintain all prior programming information.
- H. At power-on, all registers are set to a default condition. See Byte 0 detail for default condition, Bytes 1 through 5 default to a 1 (Enabled output state)

CPU_STOP# Timing Diagram

CPU_STOP# is an asynchronous input to the clock synthesizer. It is used to turn off the CPU clocks for low power operation. CPU_STOP# is synchronized by the **ICS9148-08**. The minimum that the CPU clock is enabled (CPU_STOP# high pulse) is 100 CPU clocks. All other clocks will continue to run while the CPU clocks are disabled. The CPU clocks will always be stopped in a low state and start in such a manner that guarantees the high pulse width is a full pulse. CPU clock on latency is less than 4 CPU clocks and CPU clock off latency is less than 4 CPU clocks.

Notes:

1. All timing is referenced to the internal CPU clock.
2. CPU_STOP# is an asynchronous input and metastable conditions may exist. This signal is synchronized to the CPU clocks inside the ICS9148-08.
3. All other clocks continue to run undisturbed. (including SDRAM outputs).

PCI_STOP# Timing Diagram

PCI_STOP# is an asynchronous input to the **ICS9148-08**. It is used to turn off the PCICLK (0:5) clocks for low power operation. PCI_STOP# is synchronized by the **ICS9148-08** internally. The minimum that the PCICLK (0:5) clocks are enabled (PCI_STOP# high pulse) is at least 10 PCICLK (0:5) clocks. PCICLK (0:5) clocks are stopped in a low state and started with a full high pulse width guaranteed. PCICLK (0:5) clock on latency cycles are only one rising PCICLK clock off latency is one PCICLK clock.

Notes:

1. All timing is referenced to the Internal CPUCLK (defined as inside the ICS9148 device.)
2. PCI_STOP# is an asynchronous input, and metastable conditions may exist. This signal is required to be synchronized inside the ICS9148.
3. All other clocks continue to run undisturbed.
4. CPU_STOP# is shown in a high (true) state.

Shared Pin Operation - Input/Output Pins

Pins 2, 7, 8, 25 and 26 on the **ICS9148-08** serve as dual signal functions to the device. During initial power-up, they act as input pins. The logic level (voltage) that is present on these pins at this time is read and stored into a 4-bit internal data latch. At the end of Power-On reset, (see AC characteristics for timing values), the device changes the mode of operations for these pins to an output function. In this mode the pins produce the specified buffered clocks to external loads.

To program (load) the internal configuration register for these pins, a resistor is connected to either the VDD (logic 1) power supply or the GND (logic 0) voltage potential. A 10 Kilohm(10K) resistor is used to provide both the solid CMOS programming voltage needed during the power-up programming period and to provide an insignificant load on the output clock during the subsequent operating period.

Figs. 1 and 2 show the recommended means of implementing this function. In Fig. 1 either one of the resistors is loaded onto the board (selective stuffing) to configure the device's internal logic. Figs. 2a and b provide a single resistor loading option where either solder spot tabs

or a physical jumper header may be used.

These figures illustrate the optimal PCB physical layout options. These configuration resistors are of such a large ohmic value that they do not effect the low impedance clock signals. The layouts have been optimized to provide as little impedance transition to the clock signal as possible, as it passes through the programming resistor pad(s).

Absolute Maximum Ratings

Supply Voltage.....	7.0 V
Logic Inputs.....	GND –0.5 V to $V_{DD} + 0.5$ V
Ambient Operating Temperature	0°C to +70°C
Storage Temperature	–65°C to +150°C

Stresses above those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These ratings are stress specifications only and functional operation of the device at these or any other conditions above those listed in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect product reliability.

Ordering Information

ICS9148F-08

Example:

ICS XXXX F - PPP

Pattern Number (2 or 3 digit number for parts with ROM code patterns)

Package Type
F=SSOP

Device Type (consists of 3 or 4 digit numbers)

Prefix

ICS, AV = Standard Device
