

ICL7106 / ICL7107

3½ Digit LCD/LED Display A/D Converter

PRODUCT DESCRIPTION

The ICL7106 and ICL7107 are high performance, low power, 3½ digit A/D converters. Included are seven segment decoders, display drivers, a reference, and a clock. The ICL7106 is designed to interface with a liquid crystal display (LCD) and includes a multiplexed backplane drive; the ICL7107 will directly drive an instrument size light emitting diode (LED) display.

The ICL7106 and ICL7107 bring together a combination of high accuracy, versatility, and true economy. True differential inputs and reference are useful in all systems, but give the designer an uncommon advantage when measuring load cells, strain gauges and other bridge type transducers. Finally, the true economy of single power supply operation (ICL7106), enables a high performance panel meter to be built with the addition of only 10 passive components and a display.

Display-hold, low-battery flag, integration and de-integration status flags are four additional features which are available in the 44-pin package.

FEATURES

- Guaranteed Zero Reading for 0V Input on All Scales
- True Polarity at Zero for Precise Null Detection
- True Differential Input and Reference, Direct Display Drive
 - LCD ICL7106
 - LED ICL7107
- Low Noise - Less Than 15 $\mu\text{V}_{\text{P-P}}$
- On Chip Clock and Reference
- Low Power Dissipation - Typically Less Than 10mW
- No Additional Active Circuits Required
- New Small Outline Surface Mount Package Available
- Four additional features are available for 44 pin PQFP package:
 - Display - Hold
 - Low - Battery indication
 - Integration Status indication
 - De-integration Status Indication

APPLICATIONS

These devices can be used in a wide range of digital panel meter applications. Most applications, however, involve the measurement and display of analog data:

- Pressure
- Conductance
- Voltage
- Current
- Resistance
- Speed
- Temperature
- Material Thickness

Ordering Information

PART NO.	TEMP. RANGE (°C)	PACKAGE
ICL7106CPL	0 – 70 °C	40 Ld. PDIP
ICL7106CM44	0 – 70 °C	44 Ld. PQFP
ICL7106CX	0 – 70 °C	Dice

DISPLAY DRIVER ICL7107 ONLY					
Segment Sinking Current Except Pins 19 and 20	V+ = 5V, Segment Voltage = 3V	5	8	-	mA
Pin 19 Only		10	16	-	mA
Pin 20 Only		4	7	-	mA

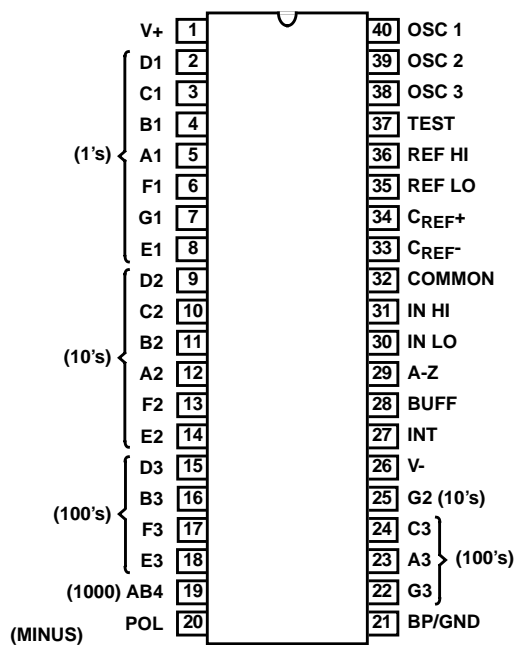

NOTES:

- Input voltages may exceed the supply voltages provided the input current is limited to ±100µA.
- θ_{JA} is measured with the component mounted on a low effective thermal conductivity test board in free air.
- Unless otherwise noted, specifications apply to both the ICL7106 and ICL7107 at $T_A = 25^\circ\text{C}$, $f_{\text{CLOCK}} = 48\text{kHz}$.
ICL7106 is tested in the circuit of Figure 1. ICL7107 is tested in the circuit of Figure 2.
- Back plane drive is in phase with segment drive for "off" segment, 180 degrees out of phase for "on" segment.
Frequency is 20 times conversion rate. Average DC component is less than 50mV.
- Not tested, guaranteed by design.

Design Information Summary Sheet• **OSCILLATOR FREQUENCY**

$$f_{OSC} = 0.45/RC$$

$$C_{OSC} > 50pF; R_{OSC} > 50k\Omega$$

$$f_{OSC} (Typ) = 48kHz$$

• **OSCILLATOR PERIOD**

$$t_{OSC} = RC/0.45$$

• **INTEGRATION CLOCK FREQUENCY**

$$f_{CLOCK} = f_{OSC}/4$$

• **INTEGRATION PERIOD**

$$t_{INT} = 1000 \times (4/f_{OSC})$$

• **60/50Hz REJECTION CRITERION**

$$t_{INT}/t_{60Hz} \text{ or } t_{INT}/t_{50Hz} = \text{Integer}$$

• **OPTIMUM INTEGRATION CURRENT**

$$I_{INT} = 4\mu A$$

• **FULL SCALE ANALOG INPUT VOLTAGE**

$$V_{INFS} (Typ) = 200mV \text{ or } 2V$$

• **INTEGRATE RESISTOR**

$$R_{INT} = \frac{V_{INFS}}{I_{INT}}$$

• **INTEGRATE CAPACITOR**

$$C_{INT} = \frac{(t_{INT})(I_{INT})}{V_{INT}}$$

• **INTEGRATOR OUTPUT VOLTAGE SWING**

$$V_{INT} = \frac{(t_{INT})(I_{INT})}{C_{INT}}$$

• **V_{INT} MAXIMUM SWING:**

$$(V_- + 0.5V) < V_{INT} < (V_+ - 0.5V), V_{INT} (Typ) = 2V$$

• **DISPLAY COUNT**

$$COUNT = 1000 \times \frac{V_{IN}}{V_{REF}}$$

• **CONVERSION CYCLE**

$$t_{CYC} = t_{CLOCK} \times 4000$$

$$t_{CYC} = t_{OSC} \times 16,000$$

when $f_{OSC} = 48kHz$; $t_{CYC} = 333ms$

• **COMMON MODE INPUT VOLTAGE**

$$(V_- + 1V) < V_{IN} < (V_+ - 0.5V)$$

• **AUTO-ZERO CAPACITOR**

$$0.01\mu F < C_{AZ} < 1\mu F$$

• **REFERENCE CAPACITOR**

$$0.1\mu F < C_{REF} < 1\mu F$$

• **V_{COM}**

Biased between V_i and V_- .

• **V_{COM} \equiv V₊ - 2.8V**

Regulation lost when V_+ to $V_- < \pm 6.8V$

If V_{COM} is externally pulled down to $(V_+ + V_-)/2$, the V_{COM} circuit will turn off.

• **ICL7106 POWER SUPPLY: SINGLE 9V**

$$V_+ - V_- = 9V$$

Digital supply is generated internally

$$V_{GND} \equiv V_+ - 4.5V$$

• **ICL7106 DISPLAY: LCD**

Type: Direct drive with digital logic supply amplitude.

• **ICL7107 POWER SUPPLY: DUAL $\pm 5.0V$**

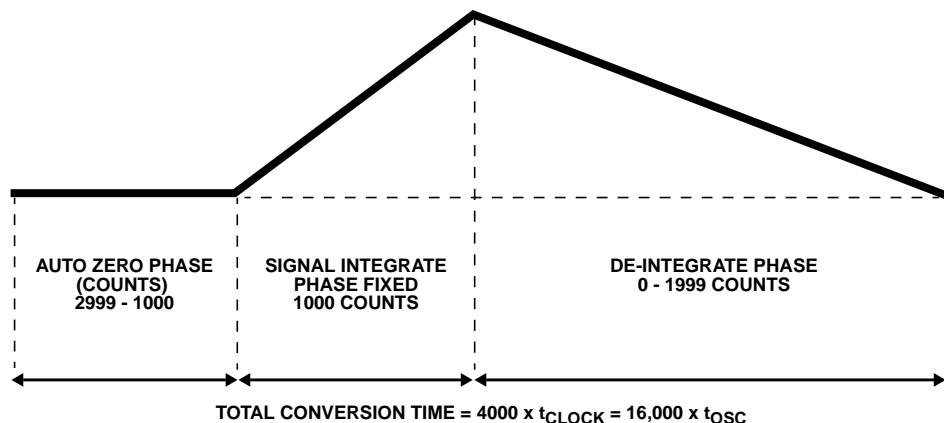

$$V_+ = +5V \text{ to GND}$$

$$V_- = -5V \text{ to GND}$$

Digital Logic and LED driver supply V_+ to GND

• **ICL7107 DISPLAY: LED**

Type: Non-Multiplexed Common Anode

Typical Integrator Amplifier Output Waveform (INT Pin)

Detailed Description

Analog Section

Figure 3 shows the Analog Section for the ICL7106 and ICL7107. Each measurement cycle is divided into three phases. They are (1) auto-zero (A-Z), (2) signal integrate (INT) and (3) de-integrate (DE).

Auto-Zero Phase

During auto-zero three things happen. First, input high and low are disconnected from the pins and internally shorted to analog COMMON. Second, the reference capacitor is charged to the reference voltage. Third, a feedback loop is closed around the system to charge the auto-zero capacitor C_{AZ} to compensate for offset voltages in the buffer amplifier, integrator, and comparator. Since the comparator is included in the loop, the A-Z accuracy is limited only by the noise of the system. In any case, the offset referred to the input is less than $10\mu\text{V}$.

Signal Integrate Phase

During signal integrate, the auto-zero loop is opened, the internal short is removed, and the internal input high and low are connected to the external pins. The converter then integrates the differential voltage between IN HI and IN LO for a fixed time. This differential voltage can be within a wide common mode range: up to 1V from either supply. If, on the other hand, the input signal has no return with respect to the converter power supply, IN LO can be tied to analog COMMON to establish the correct common mode voltage. At the end of this phase, the polarity of the integrated signal is determined.

De-Integrate Phase

The final phase is de-integrate, or reference integrate. Input low is internally connected to analog COMMON and input high is connected across the previously charged reference capacitor. Circuitry within the chip ensures that the capacitor will be connected with the correct polarity to cause the integrator output to return to zero. The time required for the

output to return to zero is proportional to the input signal. Specifically the digital reading displayed is:

$$\text{DISPLAY COUNT} = 1000 \left(\frac{V_{\text{IN}}}{V_{\text{REF}}} \right).$$

Differential Input

The input can accept differential voltages anywhere within the common mode range of the input amplifier, or specifically from 0.5V below the positive supply to 1V above the negative supply. In this range, the system has a CMRR of 86dB typical. However, care must be exercised to assure the integrator output does not saturate. A worst case condition would be a large positive common mode voltage with a near full scale negative differential input voltage. The negative input signal drives the integrator positive when most of its swing has been used up by the positive common mode voltage. For these critical applications the integrator output swing can be reduced to less than the recommended 2V full scale swing with little loss of accuracy. The integrator output can swing to within 0.3V of either supply without loss of linearity.

Differential Reference

The reference voltage can be generated anywhere within the power supply voltage of the converter. The main source of common mode error is a roll-over voltage caused by the reference capacitor losing or gaining charge to stray capacity on its nodes. If there is a large common mode voltage, the reference capacitor can gain charge (increase voltage) when called up to de-integrate a positive signal but lose charge (decrease voltage) when called up to de-integrate a negative input signal. This difference in reference for positive or negative input voltage will give a roll-over error. However, by selecting the reference capacitor such that it is large enough in comparison to the stray capacitance, this error can be held to less than 0.5 count worst case. (See Component Value Selection.)

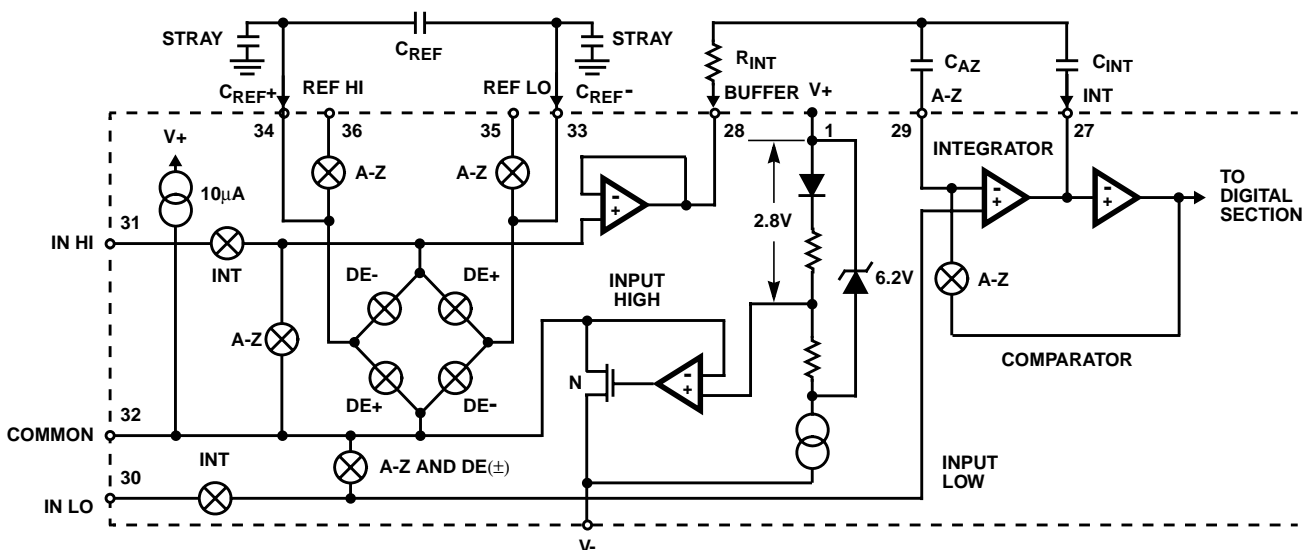

FIGURE 3. ANALOG SECTION OF ICL7106 AND ICL7107

Analog COMMON

This pin is included primarily to set the common mode voltage for battery operation (ICL7106) or for any system where the input signals are floating with respect to the power supply. The COMMON pin sets a voltage that is approximately 2.8V more negative than the positive supply. This is selected to give a minimum end-of-life battery voltage of about 6V. However, analog COMMON has some of the attributes of a reference voltage. When the total supply voltage is large enough to cause the zener to regulate ($>7V$), the COMMON voltage will have a low voltage coefficient ($0.001\%/V$), low output impedance ($\approx 15\Omega$), and a temperature coefficient typically less than $80\text{ppm}/^\circ\text{C}$.

The limitations of the on chip reference should also be recognized, however. With the ICL7107, the internal heating which results from the LED drivers can cause some degradation in performance. Due to their higher thermal resistance, plastic parts are poorer in this respect than ceramic. The combination of reference Temperature Coefficient (TC), internal chip dissipation, and package thermal resistance can increase noise near full scale from $25\mu\text{V}$ to $80\mu\text{V}_{\text{P-P}}$. Also the linearity in going from a high dissipation count such as 1000 (20 segments on) to a low dissipation count such as 1111 (8 segments on) can suffer by a count or more. Devices with a positive TC reference may require several counts to pull out of an over-range condition. This is because over-range is a low dissipation mode, with the three least significant digits blanked. Similarly, units with a negative TC may cycle between over-range and a non-over-range count as the die alternately heats and cools. All these problems are of course eliminated if an external reference is used.

The ICL7106, with its negligible dissipation, suffers from none of these problems. In either case, an external reference can easily be added, as shown in Figure 4.

Analog COMMON is also used as the input low return during auto-zero and de-integrate. If IN LO is different from analog COMMON, a common mode voltage exists in the system and is taken care of by the excellent CMRR of the converter. However, in some applications IN LO will be set at a fixed known voltage (power supply common for instance). In this application, analog COMMON should be tied to the same point, thus removing the common mode voltage from the converter. The same holds true for the reference voltage. If reference can be conveniently tied to analog COMMON, it should be since this removes the common mode voltage from the reference system.

Within the IC, analog COMMON is tied to an N-Channel FET that can sink approximately 30mA of current to hold the voltage 2.8V below the positive supply (when a load is trying to pull the common line positive). However, there is only $10\mu\text{A}$ of source current, so COMMON may easily be tied to a more negative voltage thus overriding the internal reference.

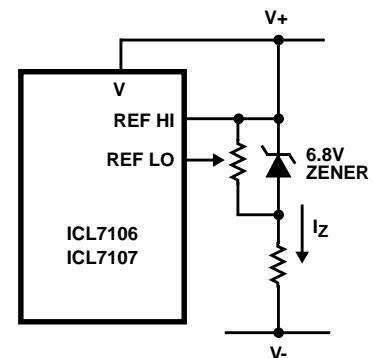

FIGURE 4A.

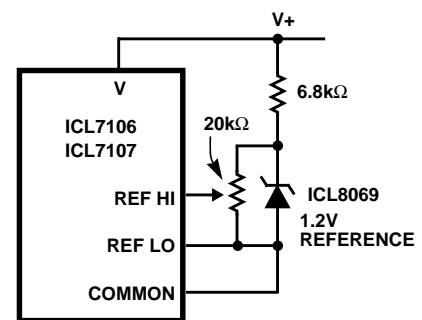

FIGURE 4B.

FIGURE 4. USING AN EXTERNAL REFERENCE

TEST

The TEST pin serves two functions. On the ICL7106 it is coupled to the internally generated digital supply through a 500Ω resistor. Thus it can be used as the negative supply for externally generated segment drivers such as decimal points or any other presentation the user may want to include on the LCD display. Figures 5 and 6 show such an application. No more than a 1mA load should be applied.

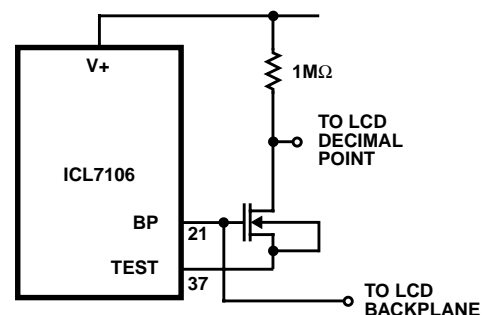

FIGURE 5. SIMPLE INVERTER FOR FIXED DECIMAL POINT

The second function is a "lamp test". When TEST is pulled high (to V+) all segments will be turned on and the display should read "1888". The TEST pin will sink about 15mA under these conditions.

CAUTION: In the lamp test mode, the segments have a constant DC voltage (no square-wave). This may burn the LCD display if maintained for extended periods.

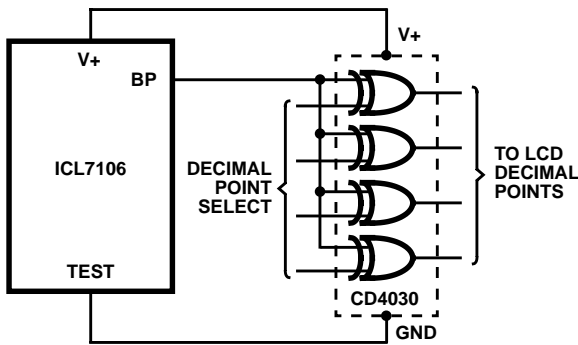

FIGURE 6. EXCLUSIVE 'OR' GATE FOR DECIMAL POINT DRIVE

Digital Section

Figures 7 and 8 show the digital section for the ICL7106 and ICL7107, respectively. In the ICL7106, an internal digital ground is generated from a 6V Zener diode and a large P-Channel source follower. This supply is made stiff to

absorb the relative large capacitive currents when the back plane (BP) voltage is switched. The BP frequency is the clock frequency divided by 800. For three readings/sec., this is a 60Hz square wave with a nominal amplitude of 5V. The segments are driven at the same frequency and amplitude and are in phase with BP when OFF, but out of phase when ON. In all cases negligible DC voltage exists across the segments.

Figure 8 is the Digital Section of the ICL7107. It is identical to the ICL7106 except that the regulated supply and back plane drive have been eliminated and the segment drive has been increased from 2mA to 8mA, typical for instrument size common anode LED displays. Since the 1000 output (pin 19) must sink current from two LED segments, it has twice the drive capability or 16mA.

In both devices, the polarity indication is "on" for negative analog inputs. If IN LO and IN HI are reversed, this indication can be reversed also, if desired.

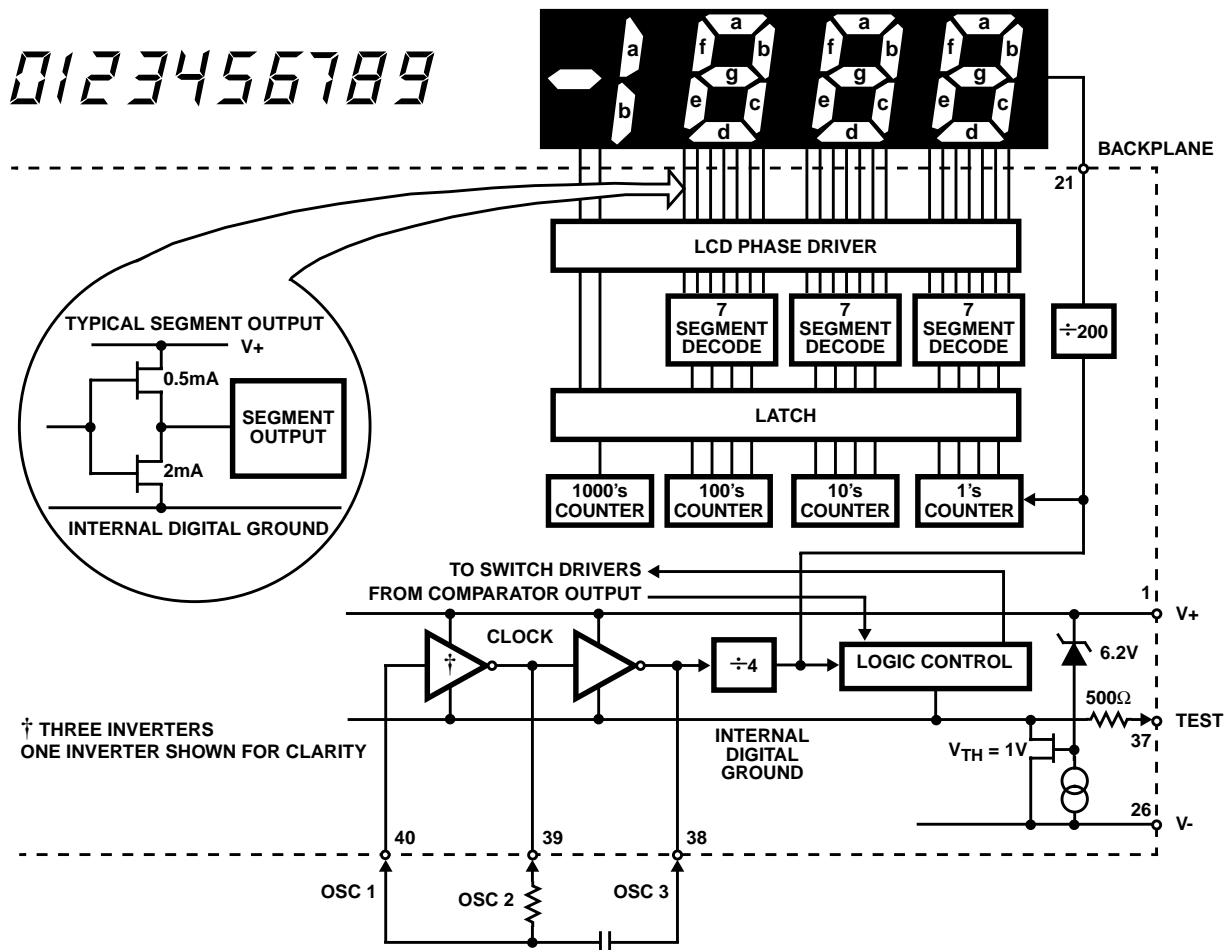

FIGURE 7. ICL7106 DIGITAL SECTION

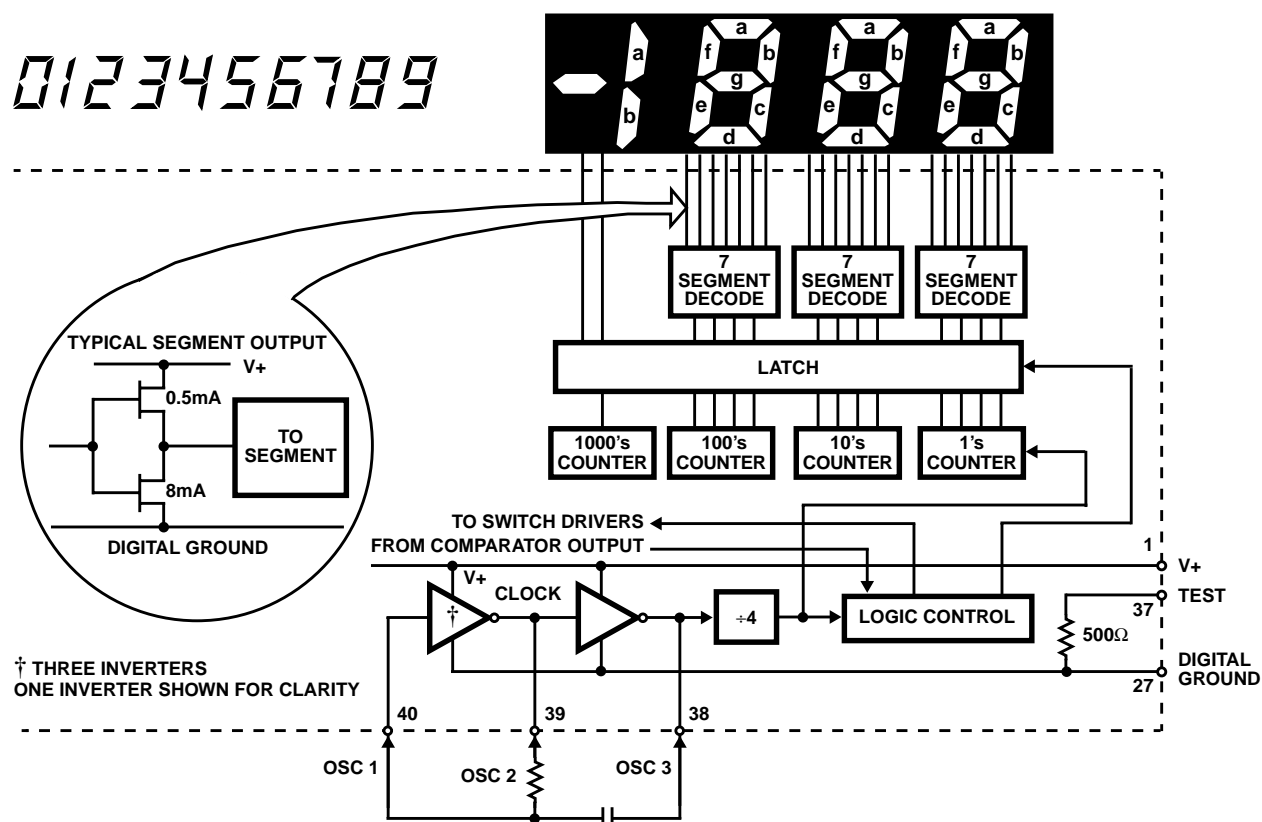

FIGURE 8. ICL7107 DIGITAL SECTION

System Timing

Figure 9 shows the clocking arrangement used in the ICL7106 and ICL7107. Two basic clocking arrangements can be used:

1. Figure 9A. An external oscillator connected to pin 40.
2. Figure 9B. An R-C oscillator using all three pins.

The oscillator frequency is divided by four before it clocks the decade counters. It is then further divided to form the three convert-cycle phases. These are signal integrate (1000 counts), reference de-integrate (0 to 2000 counts) and auto-zero (1000 to 3000 counts). For signals less than full scale, auto-zero gets the unused portion of reference de-integrate. This makes a complete measure cycle of 4,000 counts (16,000 clock pulses) independent of input voltage. For three readings/second, an oscillator frequency of 48kHz would be used.

To achieve maximum rejection of 60Hz pickup, the signal integrate cycle should be a multiple of 60Hz. Oscillator frequencies of 240kHz, 120kHz, 80kHz, 60kHz, 48kHz, 40kHz, $33\frac{1}{3}$ kHz, etc. should be selected. For 50Hz rejection, Oscillator frequencies of 200kHz, 100kHz, $66\frac{2}{3}$ kHz, 50kHz, 40kHz, etc. would be suitable. Note that 40kHz (2.5 readings/second) will reject both 50Hz and 60Hz (also 400Hz and 440Hz).

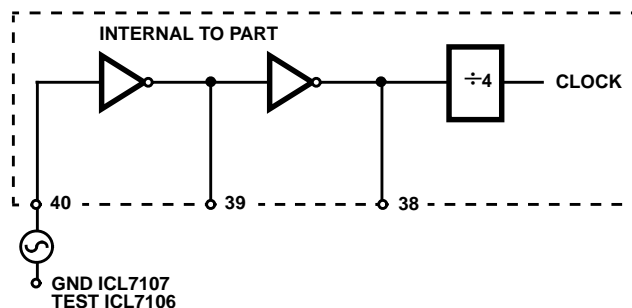

FIGURE 9A.

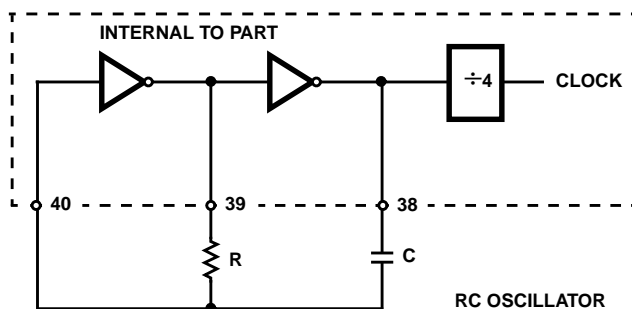

FIGURE 9B.

FIGURE 9. CLOCK CIRCUITS

Component Value Selection

Integrating Resistor

Both the buffer amplifier and the integrator have a class A output stage with 100μA of quiescent current. They can supply 4μA of drive current with negligible nonlinearity. The integrating resistor should be large enough to remain in this very linear region over the input voltage range, but small enough that undue leakage requirements are not placed on the PC board. For 2V full scale, 470kΩ is near optimum and similarly a 47kΩ for a 200mV scale.

Integrating Capacitor

The integrating capacitor should be selected to give the maximum voltage swing that ensures tolerance buildup will not saturate the integrator swing (approximately 0.3V from either supply). In the ICL7106 or the ICL7107, when the analog COMMON is used as a reference, a nominal +2V full-scale integrator swing is fine. For the ICL7107 with +5V supplies and analog COMMON tied to supply ground, a ±3.5V to +4V swing is nominal. For three readings/second (48kHz clock) nominal values for C_{INT} are 0.22μF and 0.10μF, respectively. Of course, if different oscillator frequencies are used, these values should be changed in inverse proportion to maintain the same output swing.

An additional requirement of the integrating capacitor is that it must have a low dielectric absorption to prevent roll-over errors. While other types of capacitors are adequate for this application, polypropylene capacitors give undetectable errors at reasonable cost.

Auto-Zero Capacitor

The size of the auto-zero capacitor has some influence on the noise of the system. For 200mV full scale where noise is very important, a 0.47μF capacitor is recommended. On the 2V scale, a 0.047μF capacitor increases the speed of recovery from overload and is adequate for noise on this scale.

Reference Capacitor

A 0.1μF capacitor gives good results in most applications. However, where a large common mode voltage exists (i.e., the REF LO pin is not at analog COMMON) and a 200mV scale is used, a larger value is required to prevent roll-over error. Generally 1μF will hold the roll-over error to 0.5 count in this instance.

Oscillator Components

For all ranges of frequency a 100kΩ resistor is recommended and the capacitor is selected from the equation:

$$f = \frac{0.45}{RC} \text{ For 48kHz Clock (3 Readings/sec),}$$

$$C = 100\text{pF.}$$

Reference Voltage

The analog input required to generate full scale output (2000 counts) is: $V_{IN} = 2V_{REF}$. Thus, for the 200mV and 2V scale, V_{REF} should equal 100mV and 1V, respectively. However, in many applications where the A/D is connected to a transducer, there will exist a scale factor other than unity between the input voltage and the digital reading. For instance, in a weighing system, the designer might like to have a full scale reading when the voltage from the transducer is 0.662V. Instead of dividing the input down to 200mV, the designer should use the input voltage directly and select $V_{REF} = 0.341V$. Suitable values for integrating resistor and capacitor would be 120kΩ and 0.22μF. This makes the system slightly quieter and also avoids a divider network on the input. The ICL7107 with ±5V supplies can accept input signals up to ±4V. Another advantage of this system occurs when a digital reading of zero is desired for $V_{IN} \neq 0$. Temperature and weighing systems with a variable fare are examples. This offset reading can be conveniently generated by connecting the voltage transducer between IN HI and COMMON and the variable (or fixed) offset voltage between COMMON and IN LO.

ICL7107 Power Supplies

The ICL7107 is designed to work from ±5V supplies. However, if a negative supply is not available, it can be generated from the clock output with 2 diodes, 2 capacitors, and an inexpensive IC. Figure 10 shows this application. See ICL7660 data sheet for an alternative.

In fact, in selected applications no negative supply is required. The conditions to use a single +5V supply are:

1. The input signal can be referenced to the center of the common mode range of the converter.
2. The signal is less than ±1.5V.
3. An external reference is used.

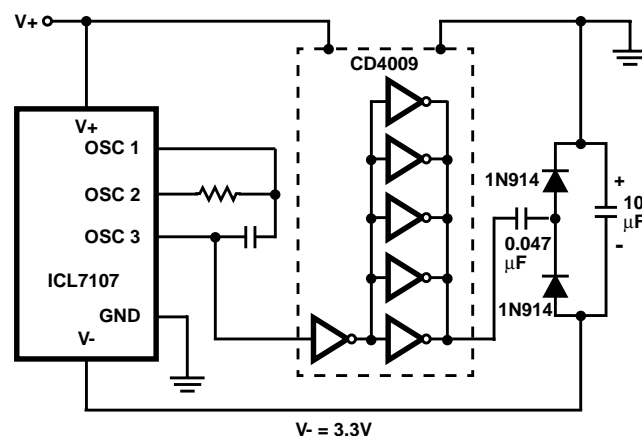

FIGURE 10. GENERATING NEGATIVE SUPPLY FROM +5V
