HD68P05V07, HD68P05M0 MCU (Microcomputer Unit)

The HD68P05 is the 8-bit Microcomputer Unit (MCU) which contains a CPU, on-chip clock, RAM, I/O and timer. It is designed for the user who needs an economical microcomputer with the proven capabilities of the HD6800-based instruction set. Setting EPROM on the package, this MCU has the equivalent function as the HD6805U and HD6805V.

- HARDWARE FEATURES
- 8-Bit Architecture
- 96 Bytes of RAM
- Memory Mapped I/O
- Internal 8-Bit Timer with 7-Bit Prescaler
- Vectored Interrupts External, Timer and Software
- 24 I/O Ports + 8 Input Port
- (8 Lines Directly Drive LEDs; 7 Bits Comparator Inputs)
- On-Chip Clock Circuit
- Master Reset
- Easy for System Development and debugging
- 5 Vdc Single Supply

SOFTWARE FEATURES

- Similar to HD6800
- Byte Efficient Instruction Set
- Easy to Program
- True Bit Manipulation
- Bit Test and Branch Instructions
- Versatile Interrupt Function
- Powerful Indexed Addressing for Tables
- Full Set of Conditional Branches
- Memory Usable as Registers/Flags
- Single Instruction Memory Examine/Change
- 10 Powerful Addressing Modes
- All Addressing Modes Apply to ROM, RAM and I/O
- Compatible Instruction Set with HD6805

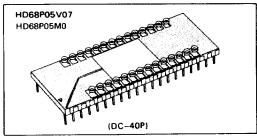

Note) EPROM is not attached to the MCU.

■ TYPE OF PRODUCTS

SIGNAL DESCRIPTION

The input and output signals for the MCU, shown in PIN ARRANGEMENT, are described in the following paragraphs.

V_{CC} and V_{SS}

Power is supplied to the MCU using these two pins. $V_{\rm CC}$ is +5.25V ±0.5V. $V_{\rm SS}$ is the ground connection.

IN'

This pin provides the capability for asynchronously applying an external interrupt to the MCU. Refer to INTERRUPTS for additional information.

XTAL and EXTAL

These pins provide connections for the on-chip clock circuit. A crystal (AT cut, 4 MHz maximum) can be connected to these pins to provide a system clock with various stability. Refer to INTERNAL OSCILLATOR for recommendations about these

inputs.

• TIMER

This pin allows an external input to be used to decrement the internal timer circuitry. Refer to TIMER for additional information about the timer circuitry.

• RES

This pin allows resetting of the MCU. Refer to RESETS for additional information.

NUM

This pin is not for user application and should be connected to $\ensuremath{V_{SS}}$.

(C) HITACHI

Input/Output Lines (A₀ ~ A₇, B₀ ~ B₇, C₀ ~ C₇)

These 24 lines are arranged into three 8-bit ports (A, B and C). All lines are programmable as either inputs or outputs under software control of the Data Direction Register (DDR). Refer to INPUT/OUTPUT for additional information.

Input Lines (D₀ ~ D₇)

These are 8-bit input lines, which has two functions. Firstly, these are TTL compatible inputs, in location \$003. The other function of them is 7 bits comparator in location \$007. Refer to INPUT for more detail.

■ REGISTERS

The MCU has five registers available to the programmer. They are shown in Figure 2 and are explained in the following paragraphs.

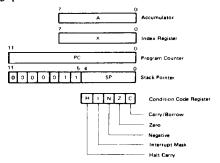

Figure 2 Programming Model

Accumulator (A)

The accumulator is a general purpose 8-bit register used to hold operands and results of arithmetic calculations or data manipulations.

Index Register (X)

The index register is an 8-bit register used for the indexed addressing mode. It contains an 8-bit address that may be added to an offset value to create an effective address. The index register can also be used for limited calculations and data manipulations when using read/modify/write instructions. When not required by a code sequence being executed, the index register can be used as a temporary storage area.

Program Counter (PC)

The program counter is a 13-bit register that contains the address of the next instruction to be executed.

Stack Pointer (SP)

The stack pointer is a 13-bit register that contains the address of the next free location on the stack. Initially, the stack pointer is set to location \$007F and is decremented as data is being pushed onto the stack and incremented as data is being pulled from the stack. The six most significant bits of the stack pointer are permanently set to 00000011. During an MCU reset or the reset stack pointer (RSP) instruction, the stack pointer is set to location \$007F. Subroutines and interrupts may be nested down to location \$0061 which allows the programmer to use up to 15 levels of subroutine calls.

Condition Code Register (CC)

The condition code register is a 5-bit register in which each bit is used to indicate or flag the results of the instruction just executed. These bits can be individually tested by a program and specific action taken as a result of their state. Each individual condition code register bit is explained in the following paragraphs.

Half Carry (H)

Used during arithmetic operations (ADD and ADC) to indicate that a carry occurred between bits 3 and 4.

Interrupt (I)

This bit is set to mask the timer and external interrupt (INT). If an interrupt occurs while this bit is set it is latched and will be processed as soon as the interrupt bit is reset.

Negative (N)

Used to indicate that the result of the last arithmetic, logical or data manipulation was negative (bit 7 in result equal to a logical one).

Zero (Z)

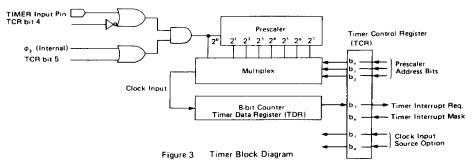

Used to indicate that the result of the last arithmetic, logical or data manipulation was zero.

Carry/Borrow (C)

Used to indicate that a carry or borrow out of the arithmetic logic unit (ALU) occurred during the last arithmetic operation. This bit is also affected during bit test and branch instructions, shifts, and rotates.

TIMER

The MCU timer circuitry is shown in Figure 3. The 8-bit counter, the Timer Data Register (TDR), is loaded under program control and counts down toward zero as soon as the clock input is applied. When the timer reaches zero, the timer interrupt request bit (bit 7) in the Timer Control Register (TCR) is set. The MCU responds to this interrpt by saving the present CPU state on the stack, fetching the timer interrupt vector from locations \$0FF8 and \$0FF9 and executing the interrupt routine. The timer interrupt can be masked by setting the timer

Hitachi America, Ltd. ● Hitachi Plaza ● 2000 Sierra Point Pkwy. ● Brisbane, CA 94005-1819 ● (415) 589-8300

interrupt mask bit (bit 6) in the TCR. The interrupt bit (I bit) in the Condition Code Register also prevents a timer interrupt from being processed.

The clock input to the timer can be from an external source applied to the TIMER input pin or it can be the internal ϕ_2 signal. When the ϕ_2 signal is used as the source, it can be gated by an input applied to the TIMER input pin allowing the user to easily perform pulse-width measurements. A prescaler option can be applied to the clock input that extends the timing interval up to a maximum of 128 counts before decrementing the counter (TDR). The timer continues to count past zero, falling through to SFF from zero and then continuing the count. Thus, the counter (TDR) can be read at any time by reading the TDR. This allows a program to determine the length of time since a time interrupt has occurred and not disturb the counting process.

The TDR is 8-bit read/write register in location \$008. At power-up or reset, the TDR and the prescaler are initialize with all logical ones.

The timer interrupt request bit (bit 7 of the TCR) is set by hardware when timer count reaches zero, and is cleared by program or by hardware reset. The bit 6 of the TCR is writable by program. Both of those bits can be read by MPU.

The bit 5 and bit 4 of the TCR select a clock input source. The selections are shown in Table 1. Bit 3 is not used. Bit 2, bit 1 and bit 0 are used to select the prescaler dividing ratio, shown in Table 2. At reset, an internal clock by the TIMER input pin is selected as clock source and "÷ 1 mode" is selected as the prescaler dividing ratio.

(NOTE) If the MCU Timer is not used, the TIMER input pin must be grounded.

Table 1 Selection of Clock Input Source

Clock Input Source	Control r (TCR)	
	Bit 5 Bit 4	
	0	0
φ ₂ Controlled by TIMER Input (Not	1	0
	0	1
Event Input from TIMER	1	1

(NOTE) 1. 0,0 and 1.0 are not usable in mask option of 6805 2. The TIMER input pin must be tied to Vcc, for uncontrolled \$\ph\$, clock.

Table 2 Selection of Prescaler Dividing Ratio

	mer Cont gister (TC		Prescaler Dividing Ratio
Bit 2	Bit 1	Bit 0	
0	0	0	Prescaler ÷ 1
0	0	1	Prescaler ÷ 2
0	1	0	Prescaler ÷ 4
0	1	1	Prescaler ÷ 8
1	0	0	Prescaler ÷ 16
1	0	1	Prescaler ÷ 32
1	1	0	Prescaler ÷ 64
1	1	1	Prescaler ÷ 128

■ RESETS

The MCU can be reset two ways; by initial power-up and by the external reset input (RES), see Figure 4. All the I/O ports are initialized to input mode (DDRs are cleared) during reset.

During power-up, a minimum 100 milliseconds is needed before allowing the RES input to go "High".

This time allows the internal crystal oscillator to stabilize. Connecting a capacitor to the RES input, as shown in Figure 5, typically provides sufficient delay.

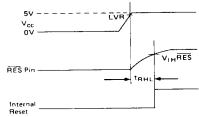

Figure 4 Power and RES Timing

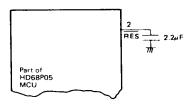

Figure 5 Power Up Reset Delay Circuit

■ INTERNAL OSCILLATOR

The internal oscillator circuit is designed to require a minimum of external components. The use of a crystal (AT cut, 4 MHz max) is sufficient to drive the internal oscillator with various stability. The different connection methods are shown in Figure 6. Crystal specifications are given in Figure 7.

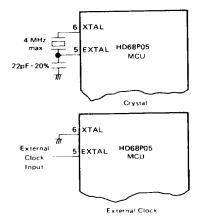

Figure 6 Internal Oscillator

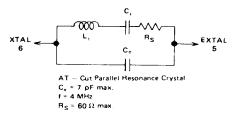

Figure 7 Crystal Parameters

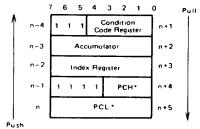

INTERRUPTS

1112

The MCU can be interrupted three different ways: through the external interrupt (INT) input pin, the internal timer interrupt request, and a software interrupt instruction (SWI). When any interrupt occurs, processing is suspended, the present CPU state is pushed onto the stack in the order shown in Fig. 8, the interrupt bit (I) in the Condition Code Register is set, the address of the interrupt routine is obtained from the appropriate interrupt vector address, and the interrupt routine is executed. Since the stack pointer decrements during pushes, the low order byte (PCL) of the program counter is stacked first; then the high order five bits (PCH) are stacked. This ensures that the program counter is loaded correctly as the stack pointer increments when it pulls data from the stack. A subroutine call will canse only the program counter (PCH, PCL) contents to be pushed

onto the stack. This interrupt bit (1) in the condition code register is set, the address of the interrupt routine is obtained from the appropriate interrupt vector address, and the interrupt routine is executed. Stacking the CPU registers, setting the I bit, and vector fetching requires 11 cycles. The interrupt service routines normally end with a return from interrupt (RTI) instruction which allows the MCU to resume processing of the program prior to the interrupt. Table 3 provides a listing of the interrupts, their priority, and the vector address that contain the starting address of the appropriate interrupt routine.

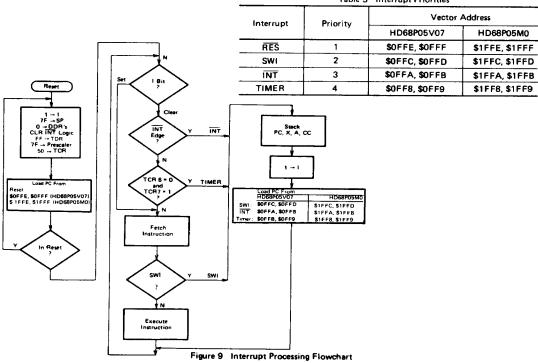

A flowchart of the interrupt processing sequence is given in Fig. 9.

* For subroutine calls, only PCH and PCL are stacked.

Figure 8 Interrupt Stacking Order

INPUT/OUTPUT

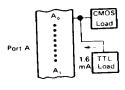

There are 24 input/output pins. All pins are programmable as either inputs or outputs under software control of the corresponding Data Direction Register (DDR). When programmed as outputs, the latched output data is readable as input data, regardless of the logic levels at the output pin due to output

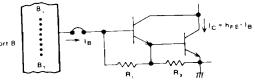

loading (see Fig. 10). When Port B is programmed for outputs, it is capable of sinking 10mA on each pin ($V_{OL}=IV$ max). All input/output lines are TTL compatible as both inputs and outputs. Port A is CMOS compatible as outputs, and Port B and C are CMOS compatible as inputs. Figure 11 provides some examples of port connections.

Data Direction Register Bit	Output Data Bit	Output State	Input to MCU
1	0	0	0
1		1	1
0		3-State	Pin

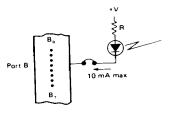

Figure 10 Typical Port I/O Circuitry

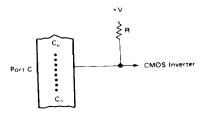

Port A Programmed as output(s), driving CMOS and TTL Load directly.

Port B Programmed as output(s), driving Darlington base directly. (b)

Port B Programmed as output(s), driving LED(s) directly.
(c)

Port C Programmed as output(s), driving CMOS loads, using external pull-up resistors. (d)

Figure 11 Typical Port Connections

INPUT

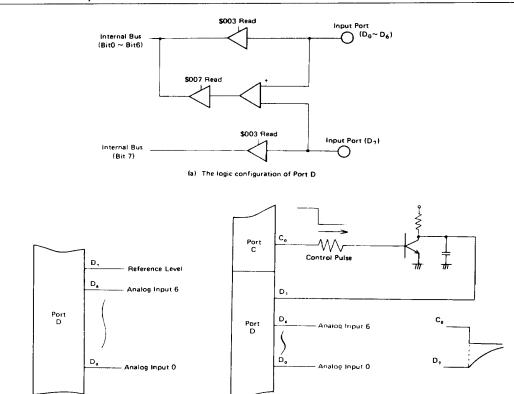

Port D can be used as either 8 TTL compatible inputs or 1 threshold input and 7 analog inputs pins. Fig. 12 (a) shows the construction of port D. The Port D register at location \$003 stores TTL compatible inputs, and those in location \$007 store the result of comparison Do to D6 inputs with D7 threshold input. Port D has not only the conventional function as inputs but also voltage-comparison function. Applying the latter, can easily check that 7 analog input electric potential max, exceeds the limit with the construction shown in Fig. 12 (b). Also, using one output pin of MCU, after external capacity is discharged at the preset state, charge the CR circuit of long enough time constant, apply the charging curve to the D7 pin. The construction described above is shown in Fig. 12 (c). The compared result of Do to Do is regularly monitored, which gives the analog input electric potential applied to Do to Do pins from inverted time. This method enables 7 inputs to be converted from analog to digital. Furthermore, combination of two functions gives 3 level voltages from Do to Do. Fig. 12 (d) provides the example when V_{TH} is set to 3.5V.

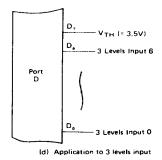

■ BIT MANIPULATION

The MCU has the ability to set or clear any single random access memory or input/output bit (except the data direction registers) with a single instruction (BSET, BCLR). Any bit in the page zero read only memory can be tested, using the BRSET and BRCLR instructions, and the program branches as a result of its state. This capability to work with any bit in RAM, ROM or I/O allows the user to have individual flags in RAM or to handle single I/O bits as control lines. The example in Figure 13 illustrates the usefulness of the bit manipulation and test instructions. Assume that bit 0 of port A is connected to a zero crossing detector circuit and that bit 1 of port A is connected to the trigger of a TRIAC which power the controlled hardware.

This program, which uses only seven ROM locations, provides turn-on of the TRIAC within 14 microseconds of the zero crossing. The timer could also be incorporated to provide turn-on at some later time which would permit pulse-width modulation of the controlled power.

■ ADDRESSING MODES

The MCU has ten addressing modes available for use by the programmer. They are explained and illustrated briefly in the following paragraphs.

Immediate

Refer to Figure 14. The immediate addressing mode accesses constants which do not change during program execution. Such instructions are two bytes long. The effective address (EA) is the PC and the operand is fetched from the byte following the opcode.

Direct

Refer to Figure 15. In direct addressing, the address of the operand is contained in the second byte of the instruction. Direct addressing allows the user to directly address the lowest 256 bytes in memory. All RAM space, I/O registers and 128 bytes of ROM are located in page zero to take advantage of this efficient memory addressing mode.

Extended

Refer to Figure 16. Extended addressing is used to reference any location in memory space. The EA is the contents of the two bytes following the opcode. Extended addressing instructions are three bytes long.

Relative

Refer to Figure 17. The relative addressing mode applies only to the branch instructions. In this mode the contents of the byte following the opcode is added to the program counter when the branch is taken. EA=(PC)+2+Rel. Rel is the contents of the location following the instruction opcode with bit 7 being the sign bit. If the branch is not taken Rel=0, when a branch takes place, the program goes to somewhere within the range of +129 bytes to -127 of the present instruction. These instructions are two bytes long.

Indexed (No Offset)

Refer to Figure 18. This mode of addressing accesses the lowest 256 bytes of memory. These instructions are one byte long and their EA is the contents of the index register.

• Indexed (8-bit Offset)

Refer to Figure 19. The EA is calculated by adding the contents of the byte following the opcode to the contents of the index register. In this mode, 511 low memory locations are accessable. These instructions occupy two bytes.

Indexed (16-bit Offset)

Refer to Figure 20. This addressing mode calculates the EA by adding the contents of the two bytes following the opcode to the index register. Thus, the entire memory space may be accessed. Instructions which use this addressing mode are three bytes long.

Bit Set/Clear

Refer to Figure 21. This mode of addressing applies to instructions which can set or clear any bit on page zero. The lower three bits in the opcode specify the bit to be set or cleared while the byte following the opcode specifies the address in page zero.

Bit Test and Branch

Refer to Figure 22. This mode of addressing applies to instructions which can test any bit in the first 256 locations (500-5FF) and branch to any location relative to the PC. The byte to be tested is addressed by the byte following the opcode. The individual bit within that byte to be tested is addressed by the lower three bits of the opcode. The third byte is the relative address to be added to the program counter if the branch condition is met. These instructions are three bytes long. The value of the bit tested is written to the carry bit in the condition code register.

Implied

Refer to Figure 23. The implied mode of addressing has no EA. All the information necessary to execute an instruction is contained in the opcode. Direct operations on the accumulator and the index register are included in this mode of addressing. In addition, control instructions such as SWI, RTI belong to this group. All implied addressing instructions are one byte long.

■ INSTRUCTION SET

The MCU has a set of 59 basic instructions. They can be divided into five different types: register/memory, read/modify/write, branch, bit manipulation, and control. The following paragraphs briefly explain each type. All the instructions within a given type are presented in individual tables.

Register/Memory Instructions

Most of these instructions use two operands. One operand is either the accumulator or the index register. The other operand is obtained from memory using one of the addressing modes. The jump unconditional (JMP) and jump to subroutine (JSR) instructions have no register operand. Refer to Table 4.

Read/Modify/Write Instructions

These instructions read a memory location or a register, modify or test its contents, and write the modified value back to memory or to the register. The test for negative or zero (TST) instruction is an exception to the read/modify/write instructions since it does not perform the write. Refer to Table

Branch Instructions

The branch instructions cause a branch from the program when a certain condition is met. Refer to Table 6.

Bit Manipulation Instructions

These instructions are used on any bit in the first 256 bytes of the memory. One group either sets or clears. The other group performs the bit test and branch operations. Refer to Table 7.

Control Instructions

The control instructions control the MCU operations during program execution, Refer to Table 8.

Alphabetical Listing

The complete instruction set is given in alphabetical order in Table 9.

Opcode Map

Table 10 is an opcode map for the instructions used on the MCU.

■ HD68P05 USED AS ROM-ON-CHIP HD6805U/V

When using the HD68P05 for the HD6805U (2k ROM) or the HD6805V (4k ROM), take the memory configuration shown in Figure 25 (a) or (b). "Not Used" or "Self Test" (\$F80 to \$FF7) locations can be used in the HD68P05. Note that these locations cannot be used for a user program when making the program in mask ROM version. The HD6805U or HD6805V takes mask option method for internal oscillation, low voltage inhibit circuit or timer. The HD68P05 takes crystal option for oscillation without low voltage inhibit circuits. The HD68P05 should specify timer part by software, so it is required to set bit 0 to bit 5 of the Timer Control Register after reset and select the prescaler dividing ratio and the clock input source. Figure 24 shows a program example where external clock is selected as an input source at 128 dividing ratio.

When the program emulated by the EPROM on package type (the HD68P05) is built in the ROM-on-chip type, the instructions operating these bits are ignored because the HD6805U/V doesn't have the TCR bit 0 to 5.

Bit 4 and 5 of the TCR should be specified to be "\$\phi_2\$ controlled by TIMER Input" or "Event Input from TIMER".

The HD6805U/V has the self test program in locations \$F80 to \$FF7 as shown in Fig. 25. The HD68P05 can use this area. But a user program written in this area cannot be built in the ROM-on-chip type. (See Table 3.) The vector address of the HD68P05M0 is \$1FF8 to \$1FFF differently from the HD6805U/V.

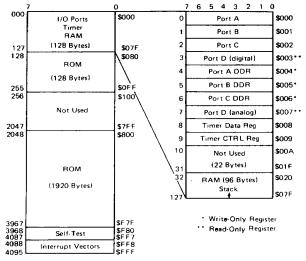

Pay attention to the above statements when debugging the program for the ROM-on-chip type.

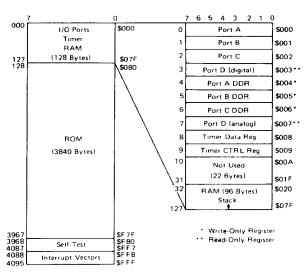

Figure 24 Example to initialize timer control register (TCR)

Underlined opcodes are marked with ____.
 The number at the bottom of each column denote the number of bytes and the number of cycles required (Bytes/Cycles).
 Mnemonics followed by a "+" require a different number of cycles as follows:

indicate that the number in parenthesis must be added to the cycle count for that instruction.

(a) HD6805U Configuration

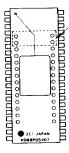

(b) HD6805V Configuration

Figure 25 MCU Memory Configuration

■ PRECAUTION TO USE EPROM ON THE PACKAGE 8-BIT SINGLE-CHIP MICROCOMPUTER

As this microcomputer takes a special packaging type with pin sockets on its surface, pay attention to the followings;

- (1) Do not apply higher electro-static voltage or serge voltage etc. than maximum rating, or it may cause permanent damage to the device.
- (2) There are 28 pin sockets on its surface. When using 32k

Let the index-side four pins open. When using 24 pin EPROM, match its index and insert it into lower 24 pin sockets.

EPROM (24 pins), let the index-side four pins open.

- (3) When assembling this LSI into user's system products as well as the mask ROM type 8-bit single-chip microcomputer, pay attention to the followings to keep the good ohmic contact between EPROM pins and pin sockets.
 - (a) When soldering on a printed circuit board, etc., keep its condition under 250°C within 10 seconds. Over-time/ temperature may cause the bonding solder of socket pins to meet and the sockets may drop.
 - (b) Keep out detergent or coater from the pin sockets at aft-solder flux removal or board coating. The flux or coater may make pin socket contactivity worse.
 - (c) Avoid the permanent use of this LSI under the evervibratory place and system.
 - (d) Repeating insertion/removal of EPROMs may damage the contactivity of the pin sockets, so it is recommended to assemble new ones to your system products.

Ask our sales agent about anything unclear.
