HD63B09, HD63C09 CMOS MPU (Micro Processing Unit)

Description

The HD6309 is the highest 8-bit microprocessor of HMCS6800 family, which is compatible with the conventional HD6809.

The HD6309 has hardware and software features which make it an ideal processor for higher level language execution or standard controller applications.

The HD6309 is complete CMOS device and its power dissipation is extremely low. Moreover, the SYNC and CWAI instruction makes low power application possible.

Features

- Hardware
 - -Interfaces with all HMCS6800 peripherals
 - -DMA transfer with no auto-refresh cycle
- Software: object code compatible with the HD6809
- Low power consumption mode (Sleep mode)
 SYNC state of SYNC Instruction
 WAIT state of CWAI Instruction
- On chip oscillator
- Wide operation range: f = 0.5 to 3 MHz ($V_{CC} = 5 \text{ V} \pm 10\%$)

Type of Products

Block Diagram

@HITACHI

Programming Model

As shown in figure 1, the HD6309 adds three registers to the set available in the HD6800. The added registers are a direct page register, the user stack pointer and a second index register.

Accumulators (A, B, D)

The A and B registers are general purpose accumulators which are used for arithmetic calculations and manipulation of data.

Certain instructions concatenate the A and B registers to form a single 16-bit accumulator. This is referred to as the D register. It is formed with the A register as the most significant byte.

Direct Page Register (DP)

The direct page register of the HD6309 serves to enhance the direct addressing mode. The contents of this register appears at the higher address outputs $(A_8 - A_{15})$ during direct addressing instruction execution. This allows the direct mode to be used at any place in memory, under program control. To ensure HD6800 compatibility, all bits of this register are cleared during processor reset.

Index Registers (X, Y)

234

The index registers are used in indexed mode addressing. The 16-bit address in this register takes

part in the calculation of effective addresses. This address may be used to point to data directly or may be modified by an optional constant or register offset. In some indexed modes, the contents of the index register are incremented or decremented to point to the next item of tabular data. All four pointer registers (X, Y, U, S) may be used as index registers.

Stack Pointer (U, S)

The hardware stack pointer (S) is used automatically by the processor during subroutine calls and interrupts. The stack pointers of the HD6309 point to the top of the stack, in contrast to the HD6800 stack pointer, which pointed to the next free location on the stack. The user stack pointer (U) is controlled exclusively by the programmer thus allowing arguments to be passed to and from subroutines with ease. Both stack pointers have the same indexed mode addressing capabilities as the X and Y registers, but also support push and pull instructions. This allows the HD6309 to be used efficiently as a stack processor, greatly enhancing its ability to support higher level languages and modular programming.

Note: The stack pointers of the HD6309 point to the top of the stack, in contrast to the HD6800 stack pointer, which pointed to the next free location on stack.

Figure 1. Programming Model of The Microprocessing Unit

@HITACHI

Program Counter (PC)

The program counter is used by the processor to point to the address of the next instruction to be executed by the processor. Relative addressing is provided allowing the program counter to be used

like an index register in some situations.

Condition Code Register (CC)

The condition code register defines the state of the processor at any given time. See figure 2.

Condition Code Register Description

Bit 0 (C)

Bit 0 is the carry flag. It is usually the carry from the binary ALU. C is also used to represent a 'borrow' from subtract-like instructions (CMP, NEG, SUB, SBC). Then, it is the complement of the carry from the binary ALU.

Bit 1 (V)

Bit 1 is the overflow flag. It is set to a one by an operation which causes a signed two's complement arithmetic overflow. This overflow is detected in an operation in which the carry from the MSB in the ALU does not match the carry from the MSB minus 1.

Bit 2 (Z)

Bit 2 is the zero flag. It is set to one if the result of the previous operation was identically zero.

Bit 3 (N)

Bit 3 is the negative flag. It contains exactly the value of the MSB of the result of the preceding operation. Thus, a negative two's-complement result will leave N set to one.

Bit 4 (I)

Bit 4 is the IRQ mask bit. The processor will not

recognize interrupts from the \overline{IRQ} line if this bit is set to one. \overline{NMI} , \overline{FIRQ} , \overline{IRQ} , \overline{RES} , and SWI all set I to one; SWI2 and SWI3 do not affect I.

Bit 5 (H)

Bit 5 is the half-carry bit. It is used to indicate a carry from bit 3 in the ALU as a result of an 8-bit addition only (ADC or ADD). This bit is used by the DAA instruction to perform a BCD decimal add adjust operation. The state of this flag is undefined in all subtract-like instructions.

Bit 6 (F)

Bit 6 is the \overline{FIRQ} mask bit. The processor will not recognize interrupts from the \overline{FIRQ} line if this bit is a one. \overline{NMI} , \overline{FIRQ} , SWI, and \overline{RES} all set F to one. \overline{IRQ} , SWI2 and SWI3 do not affect F.

Bit 7 (E)

Bit 7 is the entire flag. Set to one, it indicates that the complete machine state (all the registers) was stacked, as opposed to the subset state (PC and CC). The E bit of the stacked CC is used on a return from interrupt (RTI) to determine the extent of the unstacking. Therefore, the current E left in the condition code register represents past action.

Figure 2. Condition Code Register Format

OHITACHI

Signal Description

Power (Vss, Vcc)

Two pins supply power to the part: Vss is ground or 0 volts, while V_{CC} is $+5.0~V~\pm10\%$.

Address Bus (A₀ -A₁₅)

Sixteen pins output address information from the MPU onto the address bus. When the processor does not require the bus for a data transfer, it will output address FFFF $_{16}$, $R/\overline{W}=high$, and BS=low. This is a "dummy access" or \overline{VMA} cycle (see figures 25 and 26). All address bus drivers are made high impedance when the bus available output (BA) is high. Each pin will drive one Schottky TTL load or four LS TTL loads, and typically 90 pF.

Data Bus $(D_{\theta} - D_7)$

236

These eight pins provide communication with the system bi-directional data bus. Each pin will drive one Schottky TTL load or four LS TTL loads, and typically 130 pF.

Read/Write (R/\overline{W})

This signal indicates the direction of data transfer on the data bus. A low indicates that the MPU is writing data onto the data bus. R/\overline{W} is made high impedance when BA is high. Refer to figures 25 and 26.

Reset (RES)

A low level on this Schmitt-trigger input for greater than one bus cycle will reset the MPU, as shown in figure 3. The reset vectors are fetched from locations FFFE $_{16}$ and FFFF $_{16}$ (table 2) when interrupt acknowledge is true, ($\overline{BA} \cdot BS = 1$). During initial power-on, the reset line should be held low until the clock oscillator is fully operational. See figure 4.

Because the HD6309 reset pin has a Schmitttrigger input with a threshold voltage higher than that of standard peripherals, a simple R/C network may be used to reset the entire system. This higher

Table 1. Pin Description

| Symbol | Pin No. | I/O | Function |
|----------------------------------|---------|-----|---------------------------|
| Vss | 1 | | Ground |
| NMI | 2 | ı | Non maskable interrupt |
| ĪRQ | 3 | ı | Interrupt request |
| FIRQ | 4 | ı | Fast interrupt request |

| EXTAL, XTAL | 38, 39 | l | Oscillator connection |
| HALT | 40 | l | Halt input |

@HITACHI

threshold voltage ensures that all peripherals are out of the reset state before the processor.

Halt (HALT)

A low level on this input pin will cause the MPU to stop running at the end of the present instruction and remain halted indefinitely without loss of data. When halted, the BA output is driven high indicating the buses are high impedance. BS is also high which indicates the processor is in the halt or bus grant state. While halted, the MPU will not respond to external realtime requests (FIRQ, IRQ) although DMA/BREQ will always be accepted, and NMI or RES will be latched for later response. During the halt state, Q and E continue to run normally. If the MPU is not running (RES), a halted state (BA · BS = 1) can be achieved by pulling HALT low while RES is still low. See figure 5.

Bus Available, Bus Status (BA, BS)

The BA output is an indication of an internal control signal which makes the MOS buses of the MPU high impedance. This signal does not imply that the bus will be available for more than one cycle. When BA goes low, an additional dead cycle will elapse before the MPU acquires the bus.

The BS output signal, when decoded with BA, represents the MPU state.

Interrupt Acknowledge is indicated during both cycles of a hardware vector fetch (\overline{RES} , \overline{NMI} , \overline{FIRQ} , \overline{IRQ} , SWI, SWI2, SWI3). This signal, plus decoding of the lower four address lines, can provide the user with an indication of which interrupt level is being serviced and allow vectoring by device. See Table 2.

Sync Acknowledge is indicated while the MPU is waiting for external synchronization on an interrupt line.

Halt/Bus Grant is true when the HD6309 is in a halt or bus grant condition.

Non Maskable Interrupt (NMI)

A negative edge on $\overline{\text{NMI}}$ requests that a non-maskable interrupt sequence be generated. A non-maskable interrupt cannot be inhibited by the program, and also has a higher priority than $\overline{\text{FIRQ}}$ or software interrupts. During recognition of an $\overline{\text{NMI}}$, the entire machine state is saved on the hardware stack. After reset, an $\overline{\text{NMI}}$ will not be recognized until the first program load of the hardware stack pointer (S). The pulse width of $\overline{\text{NMI}}$ low must be at least one E cycle. If the $\overline{\text{NMI}}$ input does not meet the minimum set up with respect to Q, the interrupt will not be recognized until the next cycle See figure 6.

Figure 4. Crystal Connections and Oscillator Start Up

Figure 5. HALT and Single Instruction Execution for System Debug

(HITACHI

Figure 6. \overline{IRQ} and \overline{NMI} Interrupt Timing

Figure 7. FIRQ Interrupt Timing

Fast Interrupt Request (FIRQ)

A low level on \overline{FIRQ} input will initiate a fast interrupt sequence provided its mask bit (F) in the CC is clear. This sequence has priority over the standard interrupt request (\overline{IRQ}). It is fast in the sense that it stacks only the contents of the condition code register and the program counter. The interrupt service routine should clear the source of the interrupt before doing an RTI. See figure 7.

Interrupt Request (IRQ)

A low level input on \overline{IRQ} will initiate an interrupt request sequence provided the mask bit (I) in the CC is clear. Since \overline{IRQ} stacks the entire machine state it provides a slower response to interrupt than \overline{FIRQ} . \overline{IRQ} also has a lower priority than \overline{FIRQ} . Again, the interrupt service routine should clear the source of the interrupt before doing an RTI. See figure 6.

Note: NMI, FIRQ, and IRQ requests are sampled on the falling edge of Q. One cycle is required for synchronization before these interrupts are recognized. The pending interrupt(s) will not be serviced until completion of the current instruction unless a SYNC or CWAI condition is present. If IRQ and FIRQ do not remain low until completion of the current

instruction they may not be recognized. However, NMI is latched and need only remain low for one cycle.

XTAL, EXTAL

These two pins are connected with parallel resonant fundamental crystal, AT cut. Alternately, the pin EXTAL may be used as a TTL level input for external timing with XTAL floating. The crystal or external frequency is four times the bus frequency. See figure 4. Proper RF layout techniques should be observed in the layout of printed circuit boards.

Note for Board Design of the Oscillation Circuit: In designing the board, the following notes should be taken when the crystal oscillator is used. See figure 8.

- Crystal oscillator and load capacity Cin, Cout must be placed near the LSI as much as possible. (Normal oscillation may be disturbed when external noise is induced to pin 38 and 39.)
- Pin 38 and 39 signal line should be wired apart from other signal line as much as possible. Don't wire them in parallel with other lines. (Normal oscillation may be disturbed when E or Q signal feeds back to pin 38 and 39.)

Figure 8. Board Design of the Oscillation Circuit

@HITACHI

Designs to be Avoided: A signal line or a power source line must not cross or go near the oscillation circuit line as shown in figure 9 to prevent induction from these lines. The resistance between XTAL, EXTAL and other pins should be over $10~M\Omega$.

E, Q

E is similar to the HD6800 bus timing signal ϕ_2 : Q is a quadrature clock signal which leads E. Q has no parallel on the HD6800. Data is latched on the falling edge of E. Timing for E and Q is shown in figure 10.

Memory Ready (MRDY)

This input control signal allows stretching of E and Q to extend data-access time. E and Q operate normally while MRDY is high. When MRDY is low, E and Q may be stretched in integral multiples of half (1/2) bus cycles, thus allowing interface to slow memories, as shown in figure 11. The maximum stretch is 5 microseconds.

During nonvalid memory access (VMA cycles) MRDY has no effect on stretching E and Q: this inhibits slowing the processor during "don't care"

bus accesses. MRDY may also be used to stretch clocks (for slow memory) when bus control has been transferred to an external device (through the use of \overline{HALT} and $\overline{DMA/BREQ}$).

MRDY also stretches E and Q during dead cycles.

DMA Bus Request (DMA/BREQ)

The DMA/BREQ input provides a method of suspending execution and acquiring the MPU bus for another use, as shown in figure 12. Typical uses include DMA and dynamic memory refresh.

Transition of DMA/BREQ should occur during Q. A low level on this pin will stop instruction execution at the end of the current cycle. The MPU will acknowledge DMA/BREQ by setting BA and BS to high level. The HD6309 does not perform the auto-refresh executed in the HD6809. See figure 13.

Typically, the DMA controller will request to use the bus by asserting $\overline{DMA/BREQ}$ pin low on the leading edge of E. When the MPU replies by setting BA and BS to one, that cycle will be a dead cycle used to transfer bus mastership to the DMA controller.

Figure 9. Example of Normal Oscillation may be Disturbed

OHITACHI

2

False memory accesses may be prevented during dead cycles by developing a system \overline{DMAVMA} signal which is low in any cycle when BA has changed.

When BA goes low (a result of DMA/BREQ =

high), another dead cycle will elapse before the MPU accesses memory, to allow transfer of bus mastership without contention.

The $\overline{DMA}/\overline{BREQ}$ input should be tied high during reset state.

Figure 10. E/Q Relationship

Figure 11. MRDY Clock Stretching

MPU Operation

During normal operation, the MPU fetches an instruction from memory and then executes the requested function. This sequence begins at \overline{RES} and is repeated indefinitely unless altered by a special instruction or hardware occurrence. Soft-

ware instructions that alter normal MPU operation are: SWI, SWI2, SWI3, CWAI, RTI and SYNC. An interrupt, HALT or DMA/BREQ can also alter the normal execution of instructions. Figure 14 illustrates the flow chart for the HD6309.

Figure 12. Typical DMA Timing

Figure 13. DMA Timing

MHITACHI

245

Addressing Modes

The basic instructions of any computer are greatly enhanced by the presence of powerful addressing modes. The HD6309 has the most complete set of addressing modes available on any microcomputer today. For example, the HD6309 has 59 basic instructions, however, it recognizes 1464 different variations of instructions and addressing modes. The addressing modes support modern programming techniques. The following addressing modes are available on the HD6309:

- Implied (includes accumulator)
- Immediate
- Extended
- Extended indirect
- Direct
- Register
- Indexed
 - -Zero-offset
 - -Constant offset
 - -Accumulator offset
 - -Auto increment/decrement
- Indexed indirect
- Relative
- Program counter relative

Implied (Includes Accumulator)

In this addressing mode, the opcode of the instruction contains all the address information necessary. Examples of implied addressing are: ABX, DAA, SWI, ASRA, and CLRB.

Immediate Addressing

In immediate addressing, the effective address of the data is the location immediately following the opcode (i.e., the data to be used in the instruction immediately follows the opcode of the instruction). The HD6309 uses both 8-and 16-bit immediate values depending on the size of the argument specified by the opcode. Examples of instructions with immediate addressing are:

LDA #\$20 LDX #\$F000 LDY #CAT

Note: # signifies immediate addressing, \$ signifies hexadecimal value.

Extended Addressing

246

In extended addressing, the contents of the two bytes immediately following the opcode fully specify the 16-bit effective address used by the instruction. Note that the address generated by an extended instruction defines an absolute address and is not position independent. Examples of extended addressing include:

LDA CAT STX MOUSE LDD \$2000

Extended Indirect

As a special case of indexed addressing (discussed below), one level of indirection may be added to extended addressing. In extended indirect, the two bytes following the postbyte of an indexed instruction contain the address of the data.

LDA (CAT) LDX (\$FFFE) STU (DOG)

Direct Addressing

Direct addressing is similar to extended addressing except that only one byte of address follows the opcode. This byte specifies the lower 8 bits of the address to be used. The upper 8 bits of the address are supplied by the direct page register. Since only one byte of address is required in direct addressing, this mode requires less memory and executes faster than extended addressing. Of course, only 256 locations (one page) can be accessed without redefining the contents of the DP register. Since the DP register is set to \$00 on reset, direct addressing on the HD6309 is compatible with direct addressing on the HD6800. Indirection is not allowed in direct addressing. Some examples of direct addressing are:

LDA \$30 SETDP \$10 (Assembler directive) LDB \$1030 LDD <CAT

Note: < is 'an assembler directive which forces direct addressing.

Register Addressing

Some opcodes are followed by a byte that defines a register or set of registers to be used by the instruction. This is called a postbyte. Some examples of register addressing are:

TFR X,Y Transfers X into Y
EXG A, B Exchanges A with B
PSHS A, B, X, Y Push Y, X, B, and A onto S
PULU X, Y, D Pull D, X, and Y from U

@HITACHI

Indexed Addressing

In all indexed addressing, one of the pointer registers (X, Y, U, S, and sometimes PC) is used in a calculation of the effective address of the operand to be used by the instruction. Five basic types of indexing are available and are discussed below. The postbyte of an indexed instruction specifies the basic type and variation of the addressing mode as well as the pointer register to be used. Figure 15 lists the legal formats for the postbyte. Table 4 gives the assembler form and the number of cycles

and bytes added to the basic values for indexed addressing for each variation.

Zero-Offset Indexed: In this mode, the selected pointer register contains the effective address of the data to be used by the instruction. This is the fastest indexing mode.

Examples are:

LDD 0, X LDA S

Figure 15. Indexed Addressing Postbyte Register Bit Assignments

(C) HITACHI

HD63B09, HD63C09

Constant Offset Indexed: In this mode, a two's -complement offset and the contents of one of the pointer registers are added to form the effective address of the operand. The pointer register's initial content is unchanged by the addition.

Three sizes of offsets are available:

5-bit (-16 to +15) 8-bit (-128 to+127) 16-bit (-32768 to+32767)

The two's complement 5-bit offset is included in the postbyte and, therefore, is most efficient in use of bytes and cycles. The two's complement 8-bit offset is contained in a single byte following the postbyte. The two's complement 16-bit offset is in the two bytes following the postbyte. In most cases the programmer need not be concerned with the size of this offset since the assembler will select the optimal size automatically.

Examples of constant-offset indexing are:

LDA 23, X LDX -2, S LDY 300, X LDU CAT, Y

Accumulator Offset Indexed: This mode is similar to constant offset indexed except that the two's-complement value in one of the accumulators (A, B or D) and the contents of one of the pointer registers are added to form

Table 4. Indexed Addressing Mode

11 = S $\stackrel{+}{\sim} \text{and } _{a}^{+} \text{indicate the number of additional cycles and bytes for the particular variation.}$

@HITACHI

the effective address of the operand. The contents of both the accumulator and the pointer register are unchanged by the addition. The postbyte specifies which accumulator to use as an offset and no additional bytes are required. The advantage of an accumulator offset is that the value of the offset can be calculated by a program at run-time.

Some examples are:

| LDA | B, Y |
|------|------|
| LDX | D, Y |
| LEAX | B, X |

Auto Increment/Decrement Indexed: In the auto increment addressing mode, the pointer register contains the address of the operand. Then, after the pointer register is used it is incremented by one or two. This addressing mode is useful in stepping through tables, moving data, or for the creation of software stacks. In auto decrement, the pointer register is decremented prior to use as the address of the data. The use of auto decrement is similar to that of auto increment; but the tables, etc, are scanned from high to low addresses. The size of the increment/decrement can be either one or two to allow for tables of either 8-or 16-bit data to be accessed, selectable by the programmer. The predecrement, post-increment nature of these modes allow them to be used to create additional software stacks that behave identically to the U and S stacks.

Some examples of the auto increment/decrement addressing modes are:

| LDA | , X + |
|------|--------------|
| STD | ,Y++ |
| LDB | , Y |
| I DX | S |

Care should be taken in performing operations on 16-bit pointer registers (X, Y, U, S) where the same register is used to calculate the effective address.

Consider the following instruction:

STX
$$0, X++(X initialized to 0)$$

The desired result is to store a 0 in locations \$0000 and \$0001 then increment X to point to \$0002. In reality, the following occurs:

| 0→temp | calculate the EA; temp is a holding register | a |
|---|--|---|
| $X+2\rightarrow X$ $X\rightarrow (temp)$ | perform autoincrement do store operation | |

Indexed Indirect

All of the indexing modes with the exception of

(HITACHI

auto increment/decrement by one, or a ±4-bit offset may have an additional level of indirection specified. In indirect addressing, the effective address is contained at the location specified by the contents of the index register plus any offset. In the example below, the A accumulator is loaded indirectly using an effective address calculated from the index register and an offset.

Before Execution:

 $A = \times \times (don't care)$

After Execution:

All modes of indexed indirect are included except those which are meaningless (e.g., auto increment/decrement by 1 indirect). Some examples of indexed indirect are:

| LDA | (,X.) |
|-----|--------|
| LDD | [10,S] |
| LDA | [B,Y] |
| LDD | (X++X) |

Relative Addressing

The byte(s) following the branch opcode is (are) treated as a signed offset which may be added to the program counter. If the branch condition is true then the calculated address (PC + signed offset) is loaded into the program counter. Program execution continues at the new location as indicated by the PC. Short (1 byte offset) and long (2 bytes offset) relative addressing modes are available. All of memory can be reached in long relative addressing as an effective address is interpreted modulo 2¹⁶. Some examples of relative addressing are:

| CAT DOG | BEQ BGT LBEQ LBGT | CAT DOG RAT RABBIT | (short) (short) (long) (long) |
|---------------|----------------------------|-----------------------------|--|
| | • | | |
| | • | | |
| RAT RABBIT | NOP NOP | | |

249

Program Counter Relative

The PC can be used as the pointer register with 8 -or 16-bit signed offsets. As in relative addressing, the offset is added to the current PC to create the effective address. The effective address is then used as the address of the operand or data. Program counter relative addressing is used for writing position independent programs. Tables related to a particular routine will maintain the same relationship after the routine is moved, if referenced relative to the program counter. Examples are:

LDA CAT. PCR **LEAX** TABLE, PCR

Since program counter relative is a type of indexing, an additional level of indirection is available.

LDA [CAT, PCR] LDU [DOG, PCR]

HD6309 Instruction Set

The instruction set of the HD6309 is similar to that of the HD6800 and is upward compatible at the source code level. The number of opcodes has been reduced from 72 to 59, but because of the expanded architecture and additional addressing modes, the number of available opcodes (with different addressing modes) has risen from 197 to 1464.

Some of the instructions and addressing modes are described in detail below:

PSHU/PSHS

The push instructions can push onto either the

hardware stack (S) or user stack (U) any single register, or set of registers with a single instruction.

PULU/PULS

The pull instructions have the same capability of the push instruction, in reverse order. The byte immediately following the push or pull opcode determines which register or registers are to be pushed or pulled. The actual PUSH/PULL sequence is fixed: each bit defines a unique register to push or pull, as shown in figure 16.

Figure 16. Push and Pull Order

TFR/EXG

Within the HD6309, any register may be transferred to or exchanged with another of like-size: i. e., 8-bit to 8-bit or 16-bit to 16-bit. Bits 4-7 of the postbyte define the source register, while bits 0-3 represent the destination register (figure 17). They are denoted as follows:

| 0000-D | 0101-PC |
|----------|-----------|
| 0001 – X | 1000 - A |
| 0010 - Y | 1001 - B |
| 0011 – U | 1010-CC |
| 0100-S | 1011 – DP |

Note: All other combinations are undefined and invalid.

LEAX/LEAY/LEAU/LEAS

The LEA (load effective address) works by calculating the effective address used in an indexed instruction and stores that address value, rather than the data at that address, in a pointer register. This makes all the features of the internal addressing hardware available to the programmer. Some of the implications of this instruction are illustrated in table 5.

The LEA instruction also allows the user to access data in a position independent manner. For example:

LEAX MSG1, PCR LBSR PDATA(Print message routine)

MSG1 FCC 'MESSAGE'

This sample program prints: 'MESSAGE'. By

writing MSG1, PCR, the assembler computes the distance between the present address and MSG1. This result is placed as a constant into the LEAX instruction which will be indexed from the PC value at the time of execution. No matter where the code is located, when it is executed, the computed offset from the PC will put the absolute address of MSG1 into the X pointer register. This code is totally position independent.

The LEA instructions are very powerful and use an internal holding register (temp). Care must be exercised when using the LEA instructions with the autóincrement and autodecrement addressing modes due to the sequence of internal operations. The LEA internal sequence is outlined as follows:

| LEAa ,b+ | (any of the 16-bit pointer registers X, Y, U, or S may be substituted for a and b) |
|---------------------------|---|
| 1. b→temp | (calculate the EA) |
| 2. b + 1→b | (modify b, postincrement) |
| temp →a | (load a) |
| LEAa,-b | |
| 1. b -1 →temp | (calculate EA with prede- crement) |
| 2. $b - 1 \rightarrow b$ | (modify b, predecrement) |

(load a)

Autoincrement-by-two and autodecrement-by-two instructions work similarly. Note that LEAX, X+ does not change X, however LEAX, -X does decrement X. LEAX 1, X should be used to increment X by one.

MUL

3. temp →a

Multiplies the unsigned binary numbers in the A

Figure 17. TFR/EXG Format

| Table 5. | LEA | Examples |
|----------|-----|----------|
|----------|-----|----------|

| Instruction | Operation | Comment |
|-------------|-----------------------|-------------------------------------|
| LEAX 10, X | X+10→X | Adds 5-bit constant 10 to X |
| LEAX 500, X | X+500→X | Adds 16-bit constant 500 to X |
| LEAY A, Y | Y+A+Y | Adds 8-bit A accumula- tor to Y |
| LEAY D, Y | $Y + D \rightarrow Y$ | Adds 16-bit D accumu- lator to Y |
| LEAU-10, U | U-10 → U | Subtracts 10 from U |
| LEAS-10, S | S-10→S | Used to reserve area on stack |
| LEAS 10, S | S+10→S | Used to 'clean up' stack |
| LEAX 5, S | S+5→X | Transfers as well as adds |

@HITACHI

and B accumulator and places the unsigned result into the 16-bit D accumulator. This unsigned multiply also allows multiple-precision multiplications.

Long And Short Relative Branches

The HD6309 has the capability of program counter relative branching throughout the entire memory map. In this mode, if the branch is to be taken, the 8-or 16-bit signed offset is added to the value of the program counter to be used as the effective address. This allows the program to branch anywhere in the 64k memory map. Position independent code can be easily generated through the use of relative branching. Both short (8-bit) and long (16-bit) branches are available.

SYNC

After encountering a sync instruction, the MPU enters a sync state, stops processing instructions, and waits for an interrupt. If the pending interrupt

is non-maskable (\overline{NMI}) or maskable (\overline{FIRQ} , \overline{IRQ}) with its mask bit (F or I) clear, the processor will clear the sync state and perform the normal interrupt stacking and service routine. Since \overline{FIRQ} and \overline{IRQ} are not edge-triggered, a low level with a minimum duration of three bus cycles is required to assure that the interrupt will be taken. If the pending interrupt is maskable (\overline{FIRQ} , \overline{IRQ}) with its mask bit (F or I) set, the processor will clear the sync state and continue processing by executing the next inline instruction. Figure 18 depicts sync timing.

Software Interrupt

A software interrupt instruction will cause an interrupt, and its associated vector fetch. These software interrupts are useful in operating system calls, software debugging, trace operations, memory mapping, and software development systems. Three levels of SWI are available on this HD6309, and are prioritized in the following order: SWI, SWI3.

Figure 18. Sync Timing

16-Bit Operation

The HD6309 has the capability of processing 16-bit data. These instructions include loads, stores, compares, adds, subtracts, transfers, exchanges, pushes and pulls.

Cycle-by-Cycle Operation

The address bus cycle-by-cycle performance chart illustrates the memory-access sequence corresponding to each possible instruction and address ing mode in the HD6309. Each instruction begins with an opcode fetch. While that opcode is being internally decoded, the next program byte is always fetched. (Most instructions will use the next byte, so this technique considerably speeds throughput.) Next, the operation of each opcode will follow the flow chart. \overline{VMA} is an indication of FFFF $_{16}$ on the address bus, $R/\overline{W} = \text{high}$ and BS = low. The following examples illustrate the use of the chart: see figure 19.

Example 1: LBSR (Branch Taken)

| Before Execu | ition SP = 1 | F000 | |
|--------------|--------------|------|-----|
| | | • | |
| | | • | |
| | | • | |
| \$8000 | | LBSR | CAT |
| Ψοσσσ | | • | |
| | | • | |
| | | • | |
| \$A000 | CAT | • | |

Cycle-by-Cycle Flow

Cycle # Address Data R/W Description

| Cycle # | Addiess | Data | 10/ 11 | Description |
|---------|---------|------|--------|--|
| ī | 8000 | 17 | 1 | Opcode Fetch |
| 2 | 8001 | 1F | 1 | Offset High Byte |
| 3 | 8002 | FD | 1 | Offset Low Byte |
| 4 | FFFF | * | 1 | VMA Cycle |
| 5 | FFFF | * | 1 | VMA Cycle |
| 6 | FFFF | * | 1 | VMA Cycle |
| 7 | FFFF | * | 1 | VMA Cycle |
| 8 | EFFF | 03 | 0 | Stack Low Order |
| 9 | EFFE | 80 | 0 | Byte of Return Address Stack High Order Byte of Return Address |

Example 2: DEC (Extended)

| \$8000 | DEC | \$A000 |
|--------|-----|--------|
| \$A000 | FCB | \$80 |

Cycle-by-Cycle Flow

| Cycle # | Address | Data | R/\overline{W} | Description |
|---------|---------|------------|------------------|----------------------------|
| 1 | 8000 | 7A | 1 | Opcode Fetch |
| 2 | 8001 | A0 | 1 | Operand Address, |
| 2 | 0001 | | | High Byte |
| 3 | 8002 | 00 | 1 | Operand Address, |
| J | 0002 | | | Low Byte |
| 4 | FFFF | * | 1 | VMA Cycle |
| 5 | A000 | 80 | 1 | Read the Data |
| 6 | FFFF | * | 1 | VMA Cycle |
| 7 | A000 | 7 F | ō | Store the Decremented Data |

* The data bus has the data at that particular address.

Sleep Mode

During the interrupt wait period in the SYNC instruction (the sync state) and in the CWAI instruction (the wait state), MPU operation is halted and goes to the sleep mode. However, the state of I/O pins is the same as that of the HD6809 in this mode.

HD6309 Instruction set Tables

The instructions of the HD6309 have been broken down into five different categories. They are as follows:

- · 8-Bit operation (table 6)
- · 16-Bit operation (table 7)
- · Index register/stack pointer instructions (table 8)
- · Relative branches (long or short) (table 9)
- · Miscellaneous instructions (table 10)

HD6309 instruction set tables and Hexadecimal Values of instructions are shown in table 11 and table 12.

Table 6. 8-Bit Accumulator and Memory Instructions

| Mnemonic(s) | Operation |
|-----------------|--|
| ADCA, ADCB | Add memory to accumulator with carry |
| ADDA, ADDB | Add memory to accumulator |
| ANDA, ANDB | AND memory with accumulator |
| ASL, ASLA, ASLB | Arithmetic shift of accumulator or memory left |
| ASR, ASRA, ASRB | Arithmetic shift of accumulator or memory right |
| BITA, BITB | Bit test memory with accumulator |
| CLR, CLRA, CLRB | Clear accumulator or memory location |
| CMPA, CMPB | Compare memory from accumulator |
| COM, COMA, COMB | Complement accumulator or memory location |
| DAA | Decimal adjust A accumulator |
| DEC, DECA, DECB | Decrement accumulator or memory location |
| EORA, EORB | Exclusive OR memory with accumulator |
| EXG R1, R2 | Exchange R1 with R2 (R1, R2=A, B, CC, DP) |
| INC. INCA, INCB | Increment accumulator or memory location |
| LDA, LDB | Load accumulator from memory |
| LSL, LSLA, LSLB | Logical shift left accumulator or memory location |
| LSR, LSRA, LSRB | Logical shift right accumulator or memory location |
| MUL | Unsigned multiply (A×B→D) |
| NEG, NEGA, NEGB | Negate accumulator or memory |
| ORA, ORB | OR memory with accumulator |
| ROL, ROLA, ROLB | Rotate accumulator or memory left |
| ROR, RORA, RORB | Rotate accumulator or memory right |
| SBCA, SBCB | Subtract memory from accumulator with borrow |
| STA, STB | Store accumulator to memory |
| SUBA, SUBB | Subtract memory from accumulator |
| TST, TSTA, TSTB | Test accumulator or memory location |
| TFR R1, R2 | Transfer R1 or R2 (R1, R2=A, B, CC, DP) |

Note: A, B, CC or DP may be pushed to (pulled from) either stack with PSHS, PSHU (PULS, PULU) instructions.

HD63B09, HD63C09

Table 7. 16-Bit Accumulator and Memory Instructions

| Mnemonic(s) | Operation |
|-------------|--|
| ADDD | Add memory to D accumulator |
| CMPD | Compare memory from D accumulator |
| EXG D, R | Exchange D with X, Y, S, U or PC |
| LDD | Load D accumulator from memory |
| SEX | Sign Extend B accumulator into A accumulator |
| STD | Store D accumulator to memory |
| SUBD | Subtract memory from D accumulator |
| TFR D, R | Transfer D to X, Y, S, U or PC |
| TFR R, D | Transfer X, Y, S, U or PC to D |
| | |

Note: D may be pushed (pulled) to either stack with PSHS, PSHU (PULS, PULU) instructions.

Table 8. Index Register/Stack Pointer Instructions

| Mnemonic(s) | Operation |
|-------------|---|
| CMPS, CMPU | Compare memory from stack pointer |
| CMPX, CMPY | Compare memory from index register |
| EXG R1, R2 | Exchange D, X, Y, S, U or PC with D, X, Y, S, U or PC |
| LEAS, LEAU | Load effective address into stack pointer |
| LEAX, LEAY | Load effective address into index register |
| LDS, LDU | Load stack pointer from memory |
| LDX, LDY | Load index register from memory |
| PSHS | Push A, B, CC, DP, D, X, Y, U or PC onto hardware stack |
| PSHU | Push A, B, CC, DP, D, X, Y, S or PC onto user stack |
| PULS | Pull A, B, CC, DP, D, X, Y, U or PC from hardware stack |
| PULU | Pull A, B, CC, DP, D, X, Y, S or PC from user stack |
| STS, STU | Store stack pointer to memory |
| STX, STY | Store index register to memory |
| TFR R1, R2 | Transfer D, X, Y, S, U or PC to D, X, Y, S, U or PC |
| ABX | Add B accumulator to X (unsigned) |

Table 9. Branch Instructions

| Mnemonic(s) | Operation |
|-------------|--|
| | Simple Branches |
| BEQ, LBEQ | Branch if equal |
| BNE, LBNE | Branch if not equal |
| BMI, LBMI | Branch if minus |
| BPL, LBPL | Branch if plus |
| BCS, LBCS | Branch if carry set |
| BCC, LBCC | Branch if carry clear |
| BVS, LBVS | Branch if overflow set |
| BVC, LBVC | Branch if overflow clear |
| | Signed Branches |
| BGT, LBGT | Branch if greater (signed) |
| BGE, LBGE | Branch if greater than or equal (signed) |
| BEQ, LBEQ | Branch if equal |
| BLE, LBLE | Branch if less than or equal (signed) |
| BLT, LBLT | Branch if less than (signed) |
| | Unsigned Branches |
| вні, свні | Branch if higher (unsigned) |
| BHS, LBHS | Branch if higher or same (unsigned) |
| BEQ, LBEQ | Branch if equal |
| BLS, LBLS | Branch if lower or same (unsigned) |
| BLO, LBLO | Branch if lower (unsigned) |
| | Other Branches |
| BSR, LBSR | Branch to subroutine |
| BRA, LBRA | Branch always |
| BRN, LBRN | Branch never |
| | |

Table 10. Miscellaneous Instructions

| Mnemonic(s) | Operation |
|-----------------|--|
| ANDCC | AND condition code register |
| CWAI | AND condition code register, then wait for interrupt |
| NOP | No operation |
| ORCC | OR condition code register |
| JMP | Jump |
| JSR | Jump to subroutine |
| RTI | Return from interrupt |
| RTS | Return from subroutine |
| SWI, SWI2, SWI3 | Software interrupt (absolute indirect) |
| SYNC | Synchronize with interrupt line |

(NOTES)

This column gives a base cycle and byte count. To obtain total count, and the values obtained from the INDEXED ADDRESSING MODES table. R1 and R2 may be any pair of 8 bit or any pair of 16 bit registers.

The 8 bit registers are: A, B, CC, DP

The 16 bit registers are: X, Y, U, S, D, PC

EA is the affective address

- The bolif registers are: X, T, U, S, D, PC
 EA is the effective address.

 The PSH and PUL instructions require 5 cycle plus 1 cycle for each byte pushed or pulled.

 5(6) means: 5 cycles if branch not taken, 6 cycles if taken.

 SWI sets 1 and F bits: SW12 and SW13 do not affect I and F.

 Conditions Codes set as a direct result of the instruction.

 Value of half-carry flag is undefined.

 Special Case—Carry set if b7 is SET.

- Condition Codes set as a direct result of the instruction if CC is specified, and not affected otherwise.

(HITACHI

HD63B09, HD63C09

Note for Use

Compatibility with NMOS MPU (HD6809)

The difference between HD6309 (CMOS) and HD6809 (NMOS) is shown in table 13.

Execution Sequence of CLR Instruction

Cycle-by-cycle flow of CLR instruction (direct, extended, indexed addressing mode) is shown below. In this sequence the contents of the memory location specified by the operand is read before writing 00 into it. Note that status flags, such as IRQ Flag, will be cleared by this extra data read operation when accessing the control/status register (sharing the same address between read and write) of peripheral devices.

Example: CLR (Extended)

\$8000 CLR \$A000 \$A000 FCB \$80

| Cycle # | Address | Data | R/\overline{W} | Description |
|---------|---------|---------------|------------------|---|
| 1 | 8000 | 7 F | 1 | Opcode Fetch |
| 2 | 8001 | $\mathbf{A}0$ | 1 | Operand Address, |
| 3 | 8002 | 00 | 1 | High Byte Operand Address, Low Byte |
| 4 | FFFF | * | 1 | VMA Cycle |
| 5 | A000 | 80 | 1 | Read the Data |
| 6 | FFFF | * | 1 | VMA Cycle |
| 7 | A000 | 00 | 0 | Store Fixed 00 into Specified Location |

^{*} The data bus has the data at that particular address.

Table 13. Difference between HD6309 and HD6809

| ltem | | HD6309 (CMOS) | HD6809 (NMOS) |
|----------------|--------------|---|--|
| MRDY | Stretch Unit | integral multiples of half (1/2) bus cycles | integral multiples of quarter (1/4) bus cycles |

| | | 40 XTAL floating 38 EXTAL 4x CLK | 40 39 XTAL 777 GND 38 EXTAL 777 GND 4x CLK |

Application Note for System Design

At the trailing edge of the address bus, the noise pulses may appeare on the output signals in HD6309.

Note the noise pulses and the following measures against them.

Noise Occurrence Condition: As shown in figure 20, the noise pulses which are $0.8~\rm V$ or over may appear on E and Q clocks when the address bus changes from high to low.

If the address buses $(A_0$ - $A_{15},$ and $R/\overline{W})$ change from high to low, the transient current flows through the GND. The noise pulses are generated on the LSI's V_{SS} pins according to the current and to the impedance state of the GND wirings.

Figure 21 shows the noise voltage dependency on the each parameter.

Figure 23 shows the noise voltage dependency on

the load capacitance of the address bus.

Note: The noise level should be carefully checked because it depends on the each parameter of actual application system.

Noise Reduction:

- Control each parameter such as Cd, V _{CC}, Zg in figure 21, and the noise level is reduced to be allowable.
- 2. Insert a bypass capacitor between the V_{CC} and the GND of the HD6309.
- Connect the CMOS buffer with noise margin to E and Q clocks.
- 4. Insert the damping registors to the address bus. That is effective for the noise level to reduce less than 0.8 V. The damping resistor is about 40-50 Ω on the higher byte of the address bus (A 15 A8) and about 130-140 Ω on the lower byte of the address bus (A7 A0), and R/W as shown in figure 22. Electrical characteristics do not change by inserting the damping resistors.

Figure 20. Noise at Address Bus Output Changing

Absolute Maximum Ratings

| Item | Symbol | Value | Unit |
|------------------------------|-------------------------------|--------------|------|
| Supply Voltage | V _{cc} ¹ | -0.3 to +7.0 | V |
| Input Voltage | V _{in} ¹ | -0.3 to +7.0 | V |
| Maximum Output Current | I _o ² | 5 | mA |
| Maximum Total Output Current | $ \Sigma i_o ^3$ | 100 | mA |
| Operating Temperature | T _{opr} | -20 to +75 | °C |
| Storage Temperature | T _{stg} | -55 to +150 | °C |

Notes: 1. , With respect to V_{SS} (system GND)

- Maximum output current is the maximum currents which can flow out from one output terminal and I/O common terminal (A₀ -A₁₅, R/W, D₀ -D₇, BA, BS, Q, E).
- Maximum total output current is the total sum of output currents which can flow out simultaneously from output terminals and I/O common terminals (A_O -A₁₅, R/W, D_O -D₇, BA, BS, Q, E).
- Permanent LSI damage may occur if maximum ratings are exceeded. Normal operation should be under recommended operating conditions. If these conditions are exceeded, it could affect reliability of LSI.
