

HD63484

Advanced CRT Controller (ACRTC)

The advanced CRT controller (ACRTC) CMOS VLSI microcomputer peripheral device can display both graphics and characters on raster-scan displays. It is a new generation CRT controller based on bitmapped technology. It executes high-level commands, like Line, Ellipse, Paint, Pattern, and Copy, issued by the MPU in screen X-Y coordinates, and performs the address translation necessary to draw into frame memory. It can draw in up to 64k colors, on three split screens and an independent window, and perform area clipping and hitting.

The ACRTC controls a CRT in one of three modes: character only, graphics only, and multiplexed character/graphics modes. Therefore, the ACRTC has many applications, from character-only displays to large full-graphics systems.

The ACRTC reduces CPU software overhead and enhances system throughput.

2

- Colors: 16 bits/word
1, 2, 4, 8, 16 bits/pixel (5 types)
Monochrome to 64k colors max
- Pattern RAM: 32 bytes
- Converts logical X-Y coordinates to physical address
- Color operation and conditional drawing
- Drawing area control for hardware clipping and hitting
- Large frame-memory space
 - Maximum 2 Mbytes graphic memory and 128 kbytes character memory separate from the MPU memory
 - Maximum resolution: 4096×4096 pixels (1 bit/pixel mode)
- CRT display control
 - Split screens: three displays and one window
 - Zoom: 1 to 16 times
 - Scroll: vertical and horizontal
- Interleaved access mode for flashless display and superimposition
- External synchronization between ACRTCs or between ACRTC and external device (TV system or other controller)
- DMA interface
- Two programmable cursors
- Three scan modes
 - Non-interlaced
 - Interlace sync
 - Interlace sync and video
- Interrupt request to MPU
- 256 characters/line 32 raster/line, 4096 rasters/screen
- Maximum clock frequency: 9.8 MHz
- CMOS, single +5 V power supply

Features

- High-speed graphics
 - Drawing rate: 408 ns/pixel max (color drawing)
 - Commands: 38 commands including 23 graphic drawing commands
Dot, Line, Rectangle, Poly-line, Polygon, Circle, Ellipse, Paint, Copy, etc.

Ordering Information

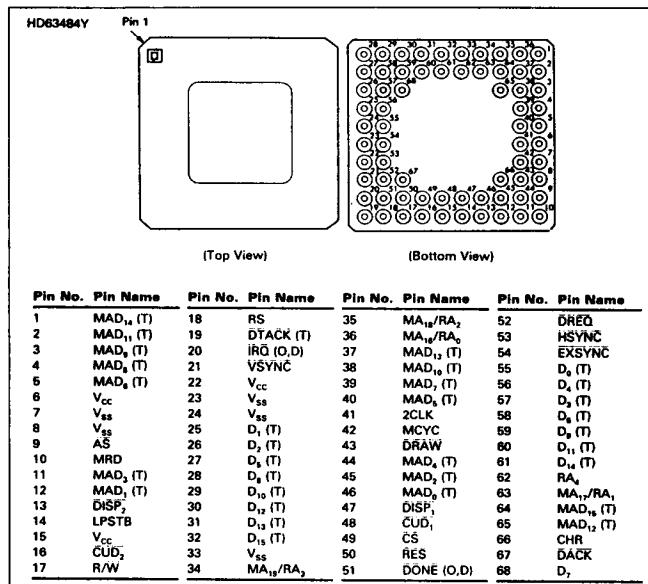

Part No.	Clock Frequency (2CLK)	Package
HD63484-4	4 MHz	DC-64
HD63484-6	6 MHz	(64-pin ceramic DIP)
HD63484-8	8 MHz	
HD63484-98	9.8 MHz	
HD63484P4	4 MHz	DP-64
HD63484P6	6 MHz	(64-pin plastic DIP)
HD63484P8	8 MHz

*: PGA pin numbers don't correspond to D₀-D₁₅, MAD₀-MAD₁₅, MA₁₆/RA₀-MA₁₉/RA₃.
Please refer to the pin arrangement.

MPU Interface

RES (Reset): RES is the MPU hardware reset.

D₀-D₁₅ (Data Bus): D₀-D₁₅ are the bidirectional data bus to/from the host MPU or DMAC. D₀-D₇ are used in 8-bit data bus mode.

R/W (Read/Write): R/W input controls the direction of host/ACRTC transfers.

CS (Chip Select): CS input enables transfers between the host and the ACRTC.

RS(Register Select): RS input selects the ACRTC register to be accessed. It is usually connected to the least significant bit of the host address bus.

DTACK (Data Transfer Acknowledge): DTACK output provides asynchronous bus cycle timing. It is compatible with the HD68000 MPU DTACK output.

IRQ (Interrupt Request): IRQ output generates interrupt service requests to the host MPU.

DMAC Interface

DREQ (DMA Acknowledge): DACK receives DMA acknowledge timing from the host DMAC.

DONE (DMA Done): DONE terminates DMA transfer. It is compatible with the HD68450 DMAC DONE signal.

CRT Interface

2CLK (Dot Clock): 2CLK is the basic ACRTC operating clock, twice the frequency of the dot clock.

MAD₀-MAD₁₅ (Frame Memory Address/Data Bus): MAD₀-MAD₁₅ are the multiplexed frame buffer address/data bus.

AS (Address Strobe): The AS output demultiplexes the address/data bus (MAD₀-MAD₁₅).

MA₁₆/RA₀-MA₁₉/RA₃ (Memory Address/Raster Address): MA₁₆/RA₀-MA₁₉/RA₃ are the upper bits of the graphics screen address multiplexed with the lower bits of the character screen raster address.

RA₄ (Raster Address): RA₄ is the high bit

of the character screen raster address (up to 32 rasters).

CHR (Character): CHR output indicates whether a graphic or character screen is being accessed.

MCYC (Memory Cycle): MCYC is the frame buffer memory access timing output, one-half the frequency of 2CLK.

MRD (Memory Read): MRD output controls the frame buffer data bus direction.

DRAW (Draw): DRAW output differentiates between drawing and CRT display refresh cycles.

DISP1, DISP2 (Display 1, 2): The DISP1 and DISP2 programmable display enable outputs can enable, disable, and blank logical screens.

CUD1, CUD2 (Cursor Display 1, 2): CUD1 and CUD2 outputs provides cursor timing programmed by ACRTC parameters such as cursor definition, cursor mode, cursor address, etc.

VSYNC (Vertical Sync): VSYNC outputs the CRT vertical synchronization pulse.

HSYNC (Horizontal Sync): HSYNC outputs the CRT horizontal synchronization pulse.

EXSYNC (External Sync): EXSYNC allows synchronization between multiple ACRTCs and other video signal generators.

LPSTB (Lightpen Strobe): LPSTB is the lightpen input.

Block Diagrams

ACRTC Functions

The ACRTC consists of 5 major functional blocks (figure 1). They operate in parallel to achieve maximum performance.

MPU Interface: The MPU interface interfaces asynchronously with the host MPU. Its functions include programmable interrupts handling, and DMA handshaking control.

CRT Interface: The CRT interface manages the frame buffer bus and the CRT timing input and output control signals. It also selects display refresh or drawing address outputs.

Drawing Processor: The drawing processor interprets commands and command parameters issued by the host bus (MPU and/or DMAC) and performs drawing operations on the frame buffer memory. It executes ACRTC drawing algorithms and converts logical X-Y addresses to physical frame buffer addresses.

It communicates with the host bus via separate 16-byte read and write FIFOs.

Display Processor: The display processor manages frame buffer refresh addressing based on the user-specified display screen organization. It combines and displays as many as 4 independent screen segments (3 horizontal split screens and 1 window) using an internal high-speed address calculation unit. It controls display refresh outputs in graphic (physical frame buffer address) or character (physical refresh memory address + row address) modes.

Timing Processor: The timing processor generates the CRT synchronization signals and signals used internally by the ACRTC.

Registers: The ACRTC registers that are visible to software are partitioned in the same way. They reside in the internal processor appropriate to their function. The registers in the display and timing processors are loaded with the basic display parameters during system initialization. During operation, the host communicates primarily with the ACRTC's drawing processor via the on-chip FIFOs.

High-Speed (= 9.8 MHz) Version of ACRTC

To keep up with the demand for improvements in the quality and resolution of CRT monitors, Hitachi has introduced a 9.8 MHz version of the HD63484 (ACRTC).

It can be used for:

1. High-resolution displays such as in office workstations, business personal computers, and CAD/CAM displays.
2. Applications requiring faster drawing than the current ACRTC with an 8-MHz 2CLK operation frequency.

High-Resolution Display

As shown in figure A, the 9.8-MHz allows the following configurations for a 4-bit/pixel system:

1. CRT monitor with 1024×808 dots, +8 DA or +4 SA
2. CRT monitor from 800×480 to 960×720 dots, +4 DA

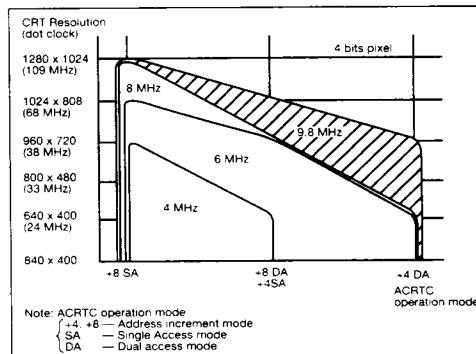

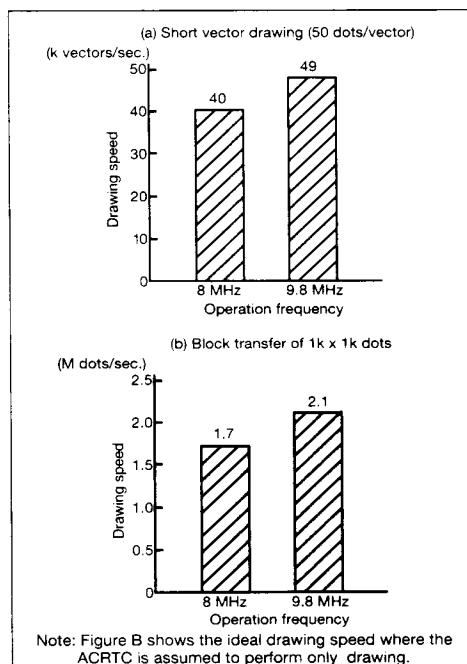

Figure A. ACRTC Operation Frequency and Supportable CRT Display Range

High-Speed Drawing Support

The ACRTC drawing speed depends on its operation frequency. Consequently it takes less time to draw with a 9.8-MHz clock than with an 8-MHz clock. Figure B compares drawing capabilities of the 9.8-MHz ACRTC and the 8-MHz ACRTC.

Note: Figure B shows the ideal drawing speed where the ACRTC is assumed to perform only drawing.

Figure B. Drawing Capability Comparison between 9.8-MHz and 8-MHz ACRTCs.

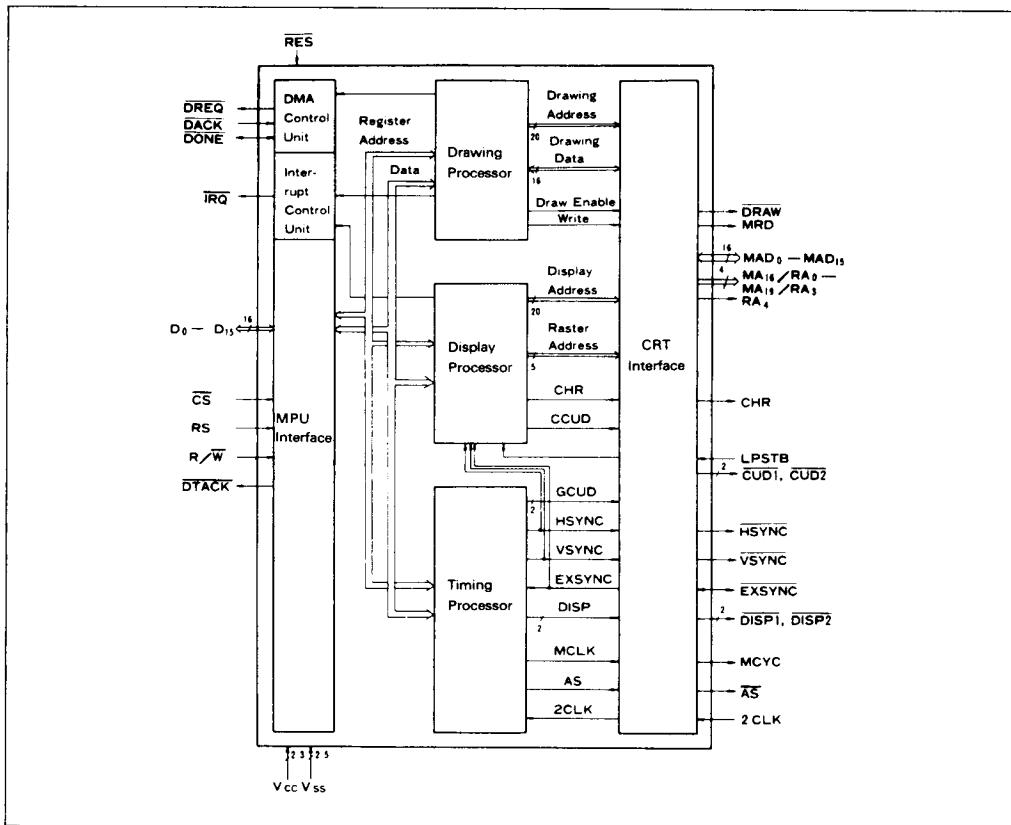

Figure 1 ACRTC Block Diagram

System Configuration

Current CRT controllers provide a single bus interface to the frame buffer that must be shared with the host MPU. However, refreshing large frame buffers, and accessing the frame buffer for drawing operations can quickly saturate the shared bus.

As shown in figure 2, the ACRTC uses separate host MPU and frame buffer interfaces. This allows the ACRTC full access to the frame buffer for display refresh and drawing operations and minimizes the ACRTC's use of the MPU system bus. A related benefit is that a large frame buffer (2 Mbyte for each ACRTC) can be used, even if the host MPU has a smaller address space or segment size restriction.

The ACRTC can use an external DMA controller. A DMA controller increases system throughput when many commands, parameters, and data must be transferred to the ACRTC. Advanced DMAC features, such as the HD68450 "chaining" modes can be used to develop powerful graphics system architectures.

However, more cost-sensitive or less performance-sensitive applications do not require a DMAC. The interface to the ACRTC can be handled under MPU software control.

While both ACRTC bus interfaces (host MPU and frame buffer) are 16 bits wide, the ACRTC also offers an 8-bit MPU mode for easy connection to popular 8-bit busses.

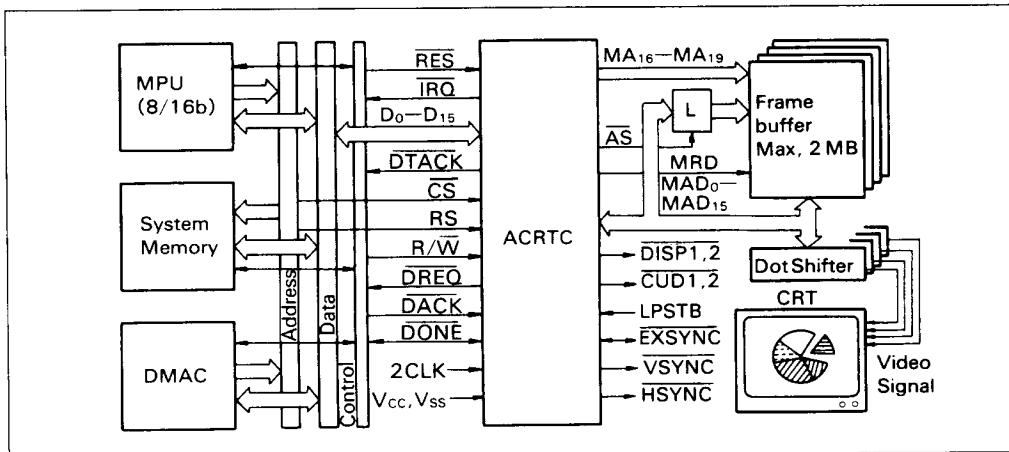

Figure 2 System Configuration

Programming Model

Address Space

The ACRTC allows the host to issue commands in logical X-Y coordinates. The ACRTC converts these physical linear word addresses with bit field offsets in the frame buffer. Figure 3 shows the relationship between the logical X-Y screen address and the frame buffer memory, which is organized as sequential 16-bit words. The host may specify logical pixels of 1, 2, 4, 8, or 16 physical bits in the frame buffer. The system in figure 3 uses 4-bit logical pixels, allowing 16 colors or tones to be selected.

Up to four logical screens (upper, base, lower, and window) are mapped onto the ACRTC physical address space. The host specifies a logical screen physical start address, logical screen physical memory width (memory words per raster), logical pixel physical memory width (bit per pixel), and the logical origin physical address. Then the ACRTC converts logical pixel X-Y addresses issued by the host MPU or the ACRTC drawing processor to physical frame buffer addresses. The ACRTC also performs bit extraction and masking to map logical pixel

operations (for example, 4 bits), to 16-bit word frame buffer addresses.

Registers

The ACRTC has over 200 bytes of accessible registers (figures 4, 5 and table 1). They are organized as hardware access, direct access, and FIFO access.

Hardware Access: The ACRTC is connected to the host MPU as a standard memory-mapped peripheral that occupies two word locations of the host's address space. The RS (register select) pin selects one of these two locations. When RS = 0 (low), read operations access the status register, and write operations access the address register.

The status register summarizes the ACRTC state. It monitors the overall state of the ACRTC for the host MPU.

When the MPU wants to access a direct access register, it puts the register's address

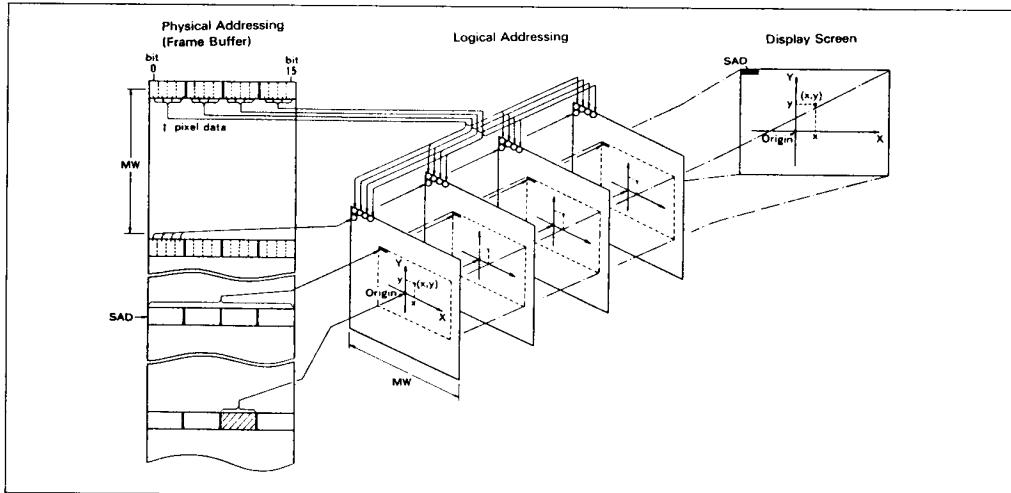

Figure 3. Logical/Physical Addressing

into the ACRTC address register.

Direct Access: The MPU accesses the direct access registers by first loading the register address into the address register. Then, when the MPU accesses the ACRTC with RS = 1 (high), the chosen register is accessed.

The FIFO entry register enables the MPU to access FIFO access registers using the ACRTC read and write FIFOs.

The command control register controls overall ACRTC operations, such as aborting or pausing commands, defining DMA protocols, and enabling/disabling interrupt sources.

The operation mode register defines basic parameters of ACRTC operation, such as frame buffer access mode, display or drawing priority, cursor and display timing skew factors, and raster scan mode.

The display control register independently enables and disables the four ACRTC logical address screens (upper, base, lower, and window). It also contains 8 user-defined video attribute bits.

The timing control RAM registers define ACRTC timing, including timing specifications for CRT control signals (HSYNC, VSYNC, etc), logical display screen size and

display period, and blink period.

The display control RAM contains registers which define logical screen display parameters, such as start address, raster address, and memory width. It also includes the cursor(s) definition, zoom factor, and lightpen registers.

FIFO Access: For high-performance drawing, key drawing processor registers are coupled to the host MPU via the ACRTC's 16-byte read and write FIFOs.

ACRTC commands are sent from the MPU via the write FIFO to the command register. As the ACRTC completes a command, the next command is automatically fetched from the write FIFO and put into the command register.

The pattern RAM defines drawing and painting patterns. It is accessed with the ACRTC's Read Pattern RAM (RPTN) and Write Pattern RAM (WPTN) register access commands.

The drawing parameter registers define detailed parameters of the drawing process, such as color data, area control (hitting/clipping), and pattern RAM pointers. The drawing parameter registers are accessed using the ACRTC's Read Parameter Register (RPR) and Write Parameter Register (WPR) commands.

Drawing Parameter Register

R: Register which can be read by Read Parameter Register Command (RPR)

W: Register which can written into by Write Parameter Register Command (WPR)

—: Access is not allowed

CL0: Defines the color data used for the drawing when logical drawing data=0

CL1: Defines the color data used for the drawing when logical drawing data=1

CCMP: Defines the comparison color of the drawing operation

PSX, PSY: Pattern Start Point

PEX, PEY: Pattern End Point

PPX, PPY: Pattern Scan Start Point

PZX, PZY: Pattern Zoom

PZCX, PZCY: Pattern Zoom Count

XMIN, YMINT: Start point of Area definition

XMAX, YMAX: End point of Area definition

Dn: Screen Number

RWPH: High-order 8 bits of Read Write Pointer Address

RWPL: Low-order 12 bits of Read Write Pointer Address

DPAH: High-order 8 bits of Drawing Pointer Address

DPAL: Low-order 12 bits of Drawing Pointer Address

DPD: Drawing Pointer Dot Address

X, Y: Position indicated by Current Pointer on X-Y coordinate

Display Functions

Logical Display Screens

The ACRTC allows the frame buffer to be divided into four separate logical screens (table 2, figure 6).

In the simplest case, only the base screen parameters must be defined. Other screens may be selectively enabled, disabled, and blanked under software control.

The background screens (upper, base, and lower) split the screen into three horizontal partitions whose positions are fully programmable. A typical application might use the base screen for the bulk of user interac-

tion, using the lower screen for a "status line(s)" and the upper screen for "pulldown menus".

The window screen is unique, since the ACRTC usually gives it higher priority than the background screens. Thus, when the window, whose size and position is completely programmable, overlaps a background screen, the window is displayed. The exception is in the ACRTC superimposed mode, in which the window has the same priority as the background screens. In this mode, the window and background screens are "superimposed" on the display.

Table 2. Logical Screen

Screen Number	Screen Name	Screen Group
0	Upper screen	Background screens
1	Base screen	
2	Low screen

Frame Memory Setup

The ACRTC can have two independent frame memories, a 2-Mbyte frame buffer and a 128-kbyte refresh memory. The CHR output controls which memory is accessed.

Frame memory width is defined by setting up the memory width register (MWR). The horizontal width is independently defined by the horizontal display register (HDR). The memory area can therefore be specified bigger than the display area (figure 7).

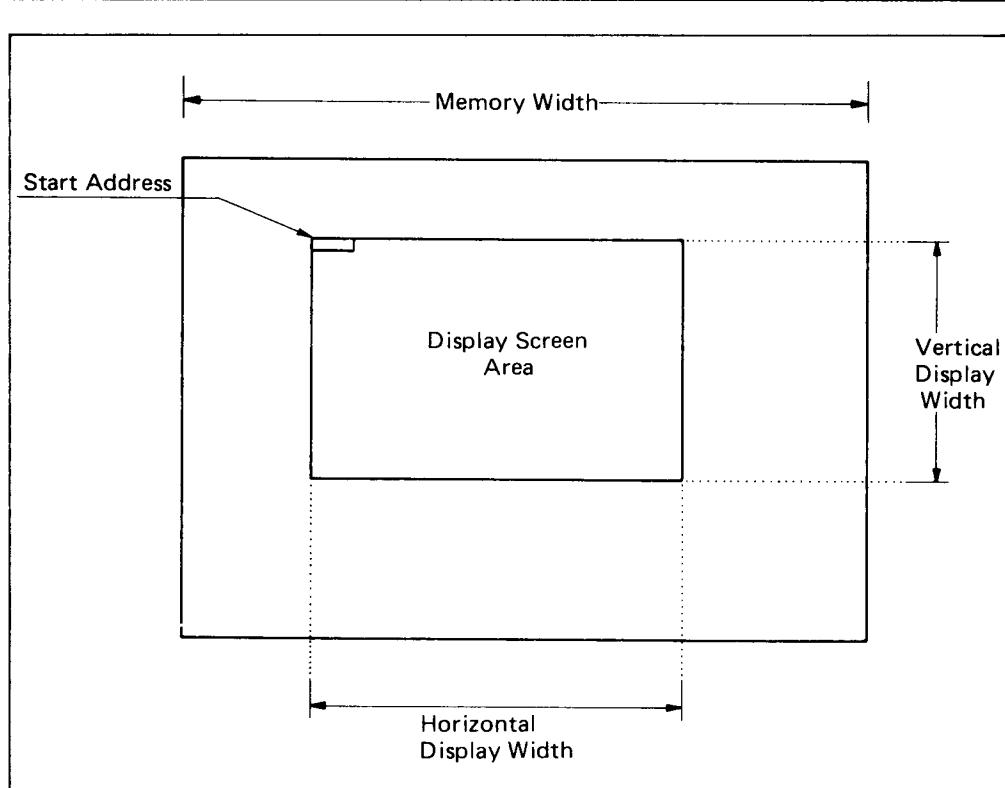

Figure 7. Frame Memory and Display Screen Area

Display Control

Figure 8 shows the relation between the frame memory and display screens. Each screen has its own memory width, vertical display width, and character/graphic attribution. These specifications are set by the control registers.

Horizontal display control registers are set in units of memory cycles. Vertical display control registers are set in units of rasters.

Note that display width of registers marked with an asterisk (*) in figure 9 is:

$$\text{(Display width)} = \text{(Register value)} + 1 \text{ memory cycles}$$

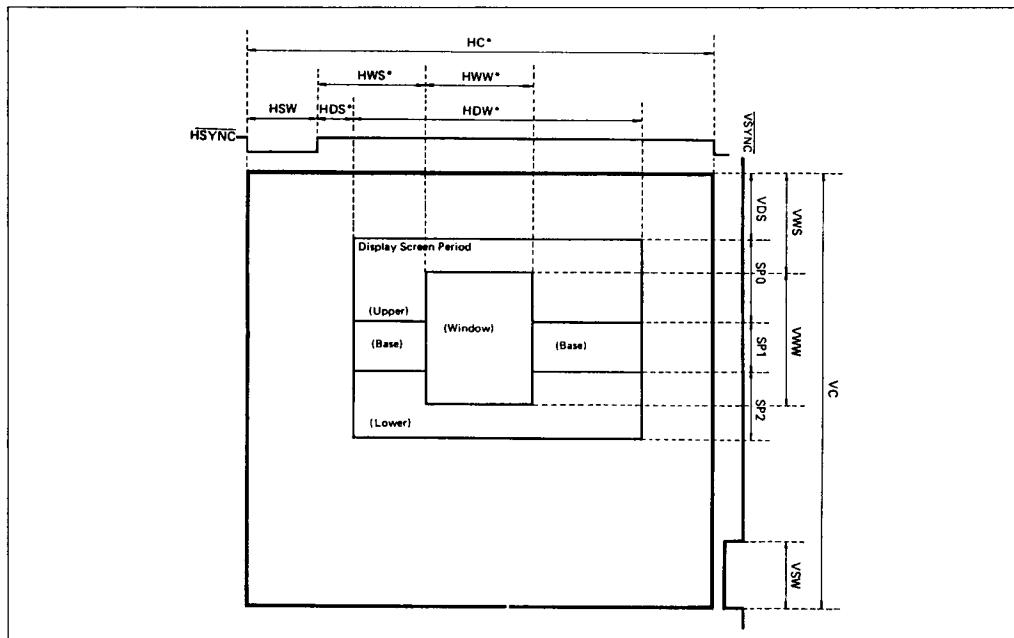

Figure 9. Display Screen Specification

Commands

The ACRTC has 38 commands classified into three groups (tables 3, 4):

- Register access
- Data transfer
- Graphic drawing

Five register access commands give the host MPU access to drawing processor drawing parameter registers and the pattern RAM.

Ten data transfer commands move data between the host system memory and the frame buffer, or within the frame buffer.

Twenty-three graphic drawing commands cause the ACRTC to draw. Parameters for these commands are specified using logical X-Y addressing.

All commands, parameters, and data are transferred via the ACRTC read and write FIFOs.

Assuming the ACRTC has been properly initialized, the MPU must perform two

steps to make the ACRTC draw:

1. First the MPU must specify drawing parameters that define the details associated with the drawing. For example, to draw a figure or paint an area, the MPU must specify the drawing or painting pattern by initializing the ACRTC pattern RAM and related pointers. If clipping or hitting control are desired, the MPU must specify the area to be monitored during drawing by initializing the area definition registers. Other drawing parameters include color, edge definition, etc.
2. After the drawing parameters have been specified, the MPU issues a drawing command and any required command parameters, such as the CRCL (circle) command with a radius parameter.

The ACRTC then performs the specified drawing operation by reading, modifying, and rewriting the contents of the frame buffer.

Table 3. ACRTC Command Table

Type	Mnemonic	Command Name	# (words)	Operation Cycles *1
Register Access Command	ORG	Origin	3	8
	WPR	Write Parameter Register	2	6
	RPR	Read Parameter Register	1	6
	WPTN	Write Pattern RAM	n+2	4n+8
	RPTN	Read Pattern RAM	2	4n+10
Data Transfer Command	DRD	DMA Read	3	(4x+8)y+12[x·y/8↑]+(62~68)
	DWT	DMA Write	3	(4x+8)y+16[x·y/8↑]+34

	RGCPY	Relative Graphic Copy	5	((P+2)A+10)B+70

- Notes: 1. 2CLK cycles.
 2. Applies to rectangular figures. Time varies for other shapes.
 3. Abbreviations

n: Number of read/write data words
 x: Number of words in X direction
 y: Number of words in Y direction
 t: Round up
 P: Operation cycles—P=4 cycles when OPM=000~011;
 P=6 cycles when OPM=100~111

L, Lo: Number of dots in a straight line

d: Total number of dots

A: Number of dots in main scan direction

B: Number of dots in sub scan direction

Notes: 1. Register access commands abbreviations

RN: Drawing parameter register number (\$0-\$13)

PRA: Pattern RAM read/write operation starting address (\$0-\$F)

DPH: Drawing pointer register high word (figure 29)

DPL: Drawing pointer register low word (figure 29)

DPAH: Higher 8 bits of drawing pointer address

DPAL: Lower 12 bits of drawing pointer address

DPD: Dot position in memory address

2. Data transfer commands abbreviations

MM: Modify mode

S: Source scan direction (figure 30)

DSD: Destination scan direction (figure 31)

AX: Number of words in X direction—1

AY: Number of words in Y direction—1

D: Write data

SAH: Source start address high word (figure 32)

SAL: Source start address low word

3. Graphic drawing commands abbreviations

AREA: Area mode

COL: Color mode

OPM: Operation mode

C: Circle drawing direction—C = 0 for counterclockwise;
C = 1 for clockwise

E: Edge color definition—E = 0, edge color is data in edge color register;
 E = 1, edge color is any color except data in color register
 SL: Slant (figure 33)
 SD: Scan direction (figure 33)
 S: Source scan direction (figure 30)
 DSD: Destination scan direction (figure 31)

4. Parameter abbreviations

- X, X₁, ..., X_n: Absolute X address from origin point
- Y, Y₁, ..., Y_n: Absolute Y address from origin point
- dX: Relative X address from current pointer
- dY: Relative Y address from current pointer
- n: Number of nodes
- dX₁, ..., dX_n: Relative X address from each node
- dY₁, ..., dY_n: Relative Y address from each node
- r: Number of dots on radius
- a, b: ratio of dX squared to dY squared in ellipse—a:b = dX²:dY²
- DX: X-direction dot number
- DY: Y-direction dot number
- Xc: Absolute X address of center point of arc/ellipse
- Yc: Absolute Y address of center point of arc/ellipse
- dXc: Relative X address from current point to center point of arc/ellipse
- dYc: Relative Y address from current point to center point of arc/ellipse
- Xe: Absolute X address of end point of arc/ellipse
- Ye: Absolute Y address of end point of arc/ellipse
- dXe: Relative X address from current point to end point of arc/ellipse
- dYe: Relative Y address from current point to end point of arc/ellipse
- Xs: Absolute X address of start point of arc/ellipse
- Ys: Absolute Y address of start point of arc/ellipse
- dXs: Relative X address from current point to start point of arc/ellipse
- dYs: Relative Y address from current point to start point of arc/ellipse

Program Transfer

For program transfer, the MPU specifies the FIFO entry address and then writes commands/parameters to the write FIFO under program control (RS = high, R/W, CS = low). The MPU writes are normally synchronized with FIFO status by software polling or interrupt.

Software Polling: WFR, WFE interrupts are disabled.

1. MPU program checks the SR (status register) for write FIFO ready flag (WFR) = 1, then writes 1 command/parameter word.
2. MPU program checks the SR (status register) for write FIFO empty flag (WFE) = 1, then writes 1 to 8 command/parameter words.

Interrupt Driven: WFR, WFE interrupts are enabled.

1. MPU WFR interrupt service routine writes 1 command/parameter word.
2. MPU WFE interrupt service routine writes 1 to 8 command/parameter words.

Register Access Commands: When writing register access commands to an in-

itially empty write FIFO, the MPU does not have to synchronize to write FIFO status. The ACRTC can fetch and execute these commands faster than the MPU can issue them.

Command DMA Transfer

Commands and parameters can be transferred from the MPU system memory by an external DMAC. The MPU initiates and terminates command DMA transfer under software control (CDM bit of CCR). Command DMA transfer can also be terminated by asserting the ACRTC DONE signal. DONE is an input in command DMA transfer mode.

In command DMA transfer mode, the ACRTC issues cycle stealing DMA requests to the DMAC when the write FIFO is ready. The DMA data is automatically sent from system memory to the ACRTC write FIFO regardless of the contents of the address register.

Make sure that the write FIFO is empty and all previous commands are terminated before starting the command DMA transfer.

Data DMA transfer cannot be executed in command DMA transfer mode.

Table 5. Register Access Commands

Command	Function
ORG	Initialize the relation between the origin point in the X-Y coordinates and the physical address
WPR	Write into parameter register
RPR	Read the parameter register
WPTN	Write into pattern RAM
RPTN	Read pattern RAM

Register Access Commands

Registers associated with the drawing processor (pattern RAM and drawing parameter registers) are accessed through the read and write FIFOs using register access commands (table 5).

Data Transfer Commands

Data transfer commands move blocks of data between the MPU system memory and the ACRTC frame buffer, or within the frame buffer itself (table 6). Before issuing these commands, a physical 20-bit frame buffer address must be specified in the

RWP (read/write pointer) drawing parameter register.

Graphic Drawing Commands

The ACRTC has 23 graphic drawing commands (table 7). Graphic drawing is performed by modifying the contents of the frame buffer based on microcoded drawing algorithms in the ACRTC drawing processor.

Most drawing coordinate parameters are specified by logical pixel X-Y addresses. The ACRTC high-speed hardware performs the complex task of translating a logical pixel address to a linear frame buffer word address, and further, selecting the proper subfield of the word (for example, a 4-bit logical pixel might reside in bits 8-11 of a certain frame buffer word).

Many instructions allow specification in either absolute or relative X-Y coordinates (for example, ALINE and RLINE). In both cases, two's complement numbers represent both positive and negative values.

Table 6. Data Transfer Commands

Command	Function
DRD	Transfer data, by DMA transfer, from the frame buffer to the MPU system memory
DWT	Transfer data, by DMA transfer, from the MPU system memory to the frame buffer
DMOD	Transfer data, by DMA transfer, from the MPU system to the frame buffer subject to logical modification (bit maskable)
RD	Read one word of data from the frame buffer specified by the read/write pointer (RWP), and load the word into read FIFO
WT	Write one word of data to the frame buffer specified by the read/write pointer (RWP)
MOD	Perform logical operation on one word in the frame buffer specified by the read/write pointer (RWP) (bit maskable)
CLR	Clear a rectangular area of the frame buffer with data in the command parameter
SCLR	Initialize a rectangular area of the frame buffer with 1-word data subject to logical operation (bit maskable)
CPY	Copy frame buffer data from one area (source area) to another area (destination area) specified by the read/write pointer (RWP)
SCPY	Copy frame buffer data from one area (source area) to another area (destination area) subject to logical modification by word. The source and destination areas must reside on the same screen (bit maskable)

Table 7. Graphic Drawing Commands

Command	Function
AMOVE	Move the current pointer (CP) to an absolute logical pixel X-Y address
RMOVE	Move the current pointer (CP) to a relative logical pixel X-Y address
ALINE	Draw a straight line from the current pointer (CP) to a command-specified end point in absolute coordinates
RLINE	Draw a straight line from the current pointer (CP) to a command-specified end point in relative coordinates
ARCT	Draw a rectangle defined by the current pointer (CP) and a command-specified diagonal point in absolute coordinates
RRCT	Draw a rectangle defined by the current pointer (CP) and a command-specified diagonal point in relative coordinates
APLL	Draw a polyline (multiple contiguous segments) from the current pointer (CP) through command-specified points in absolute coordinates
RPLL	Draw a polyline (multiple contiguous segments) from the current pointer (CP) through command-specified points in relative coordinates
APLG	Draw a polygon which connects the current pointer (CP) and command-specified points in absolute coordinates
RPLG	Draw a polygon which connects the current pointer (CP) and command-specified points in relative coordinates
CRCL	Draw a circle of radius R placing the current pointer (CP) at the center
ELPS	Draw a ellipse whose shape is specified by command parameters, placing the current pointer (CP) at the center
AARC	Draw an arc by using the current pointer (CP) as a start point with an end point and a center point in absolute coordinates
RARC	Draw an arc by using the current pointer (CP) as a start point with an end point and a center point in relative coordinates
AEARC	Draw an ellipse arc by using the current pointer (CP) as a start point with an end point and a center point in absolute coordinates
REARC	Draw an ellipse arc by using the current pointer (CP) as a start point with an end point and a center point in relative coordinates
AFRCT	Paint a rectangular area specified by the current pointer (CP) and command parameters (absolute coordinates) according to a figure pattern stored in the pattern RAM (tiling)
RFRCT	Paint a rectangular area specified by the current point (CP) and command parameters (relative coordinates) according to a figure pattern stored in the pattern RAM (tiling)
PAINT	Paint a closed area surrounded by edge color using a figure pattern stored in the pattern RAM (tiling)
DOT	Mark a dot on the coordinates indicated by the current pointer (CP)
PTN	Draw a graphic pattern defined in the pattern RAM onto a rectangular area specified by the current point (CP) and by the pattern size (rotation angle: 45°)
AGCPY	Copy a rectangular area specified by the absolute coordinates to the address specified by the current pointer (CP) (rotation angle: 90°/mirror reflection)
RGCPY	Copy a rectangular area specified by the relative coordinates to the address specified by the current pointer (CP) (rotation angle: 90°/mirror reflection)

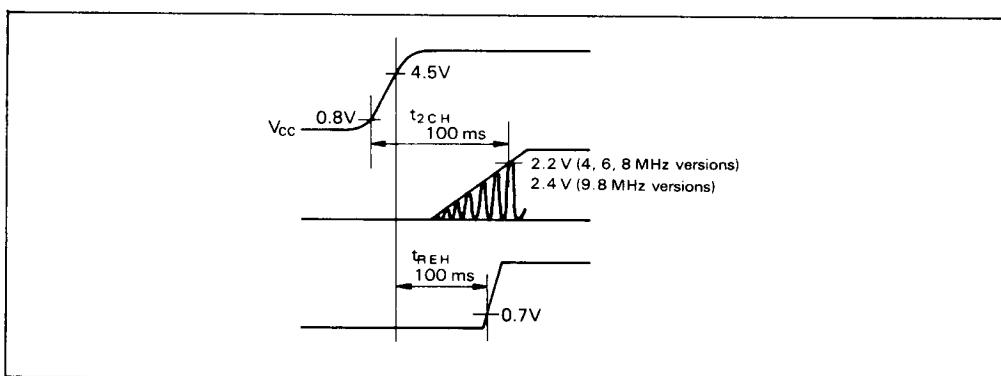

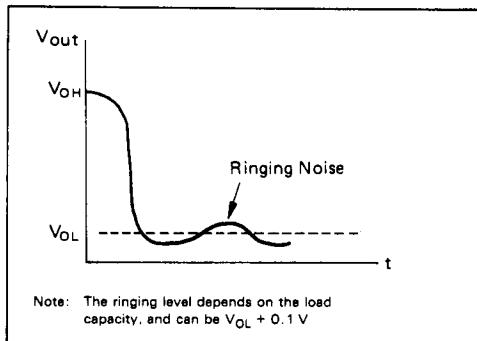

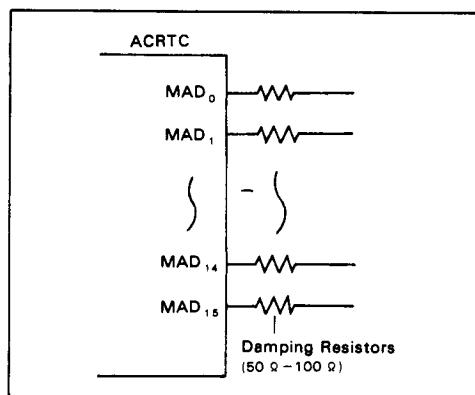

Notes on System Design**Power-On Sequence**

The conditions in figure 10 must be satisfied at power-on.

Output Waveform

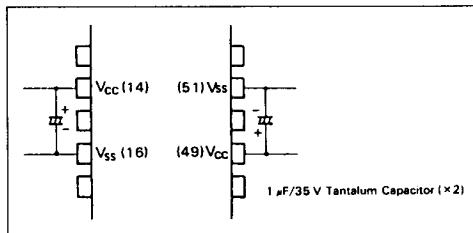

If excessive ringing (figure 11) occurs on CRT data buses, ($\text{MAD}_0\text{-}\text{MAD}_{15}$, $\text{MA}_{16}/\text{RA}_0\text{-}\text{MA}_{19}/\text{RA}_4$), damping resistors may be required as shown in figure 12.

**Figure 10. Power-On Sequence****Figure 11. Ringing Noise****Figure 12. Damping Resistors**

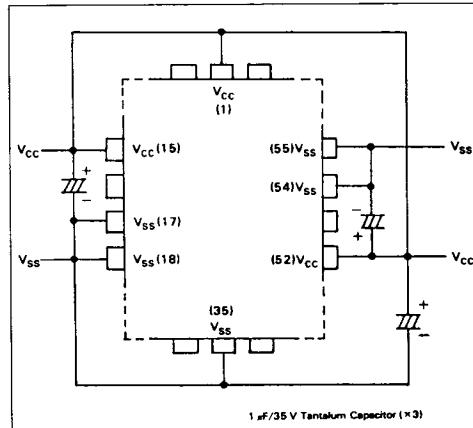

Power Supply Circuit

When laying out the V_{CC} and V_{SS} traces on

the circuit board, locate capacitors as close as possible to each power supply pin (figures 13, 14, 15).

**Figure 13. Power Supply Circuit Example,
64-Pin DIP**

**Figure 14. Power Supply Circuit Example,
68-Pin PLCC**

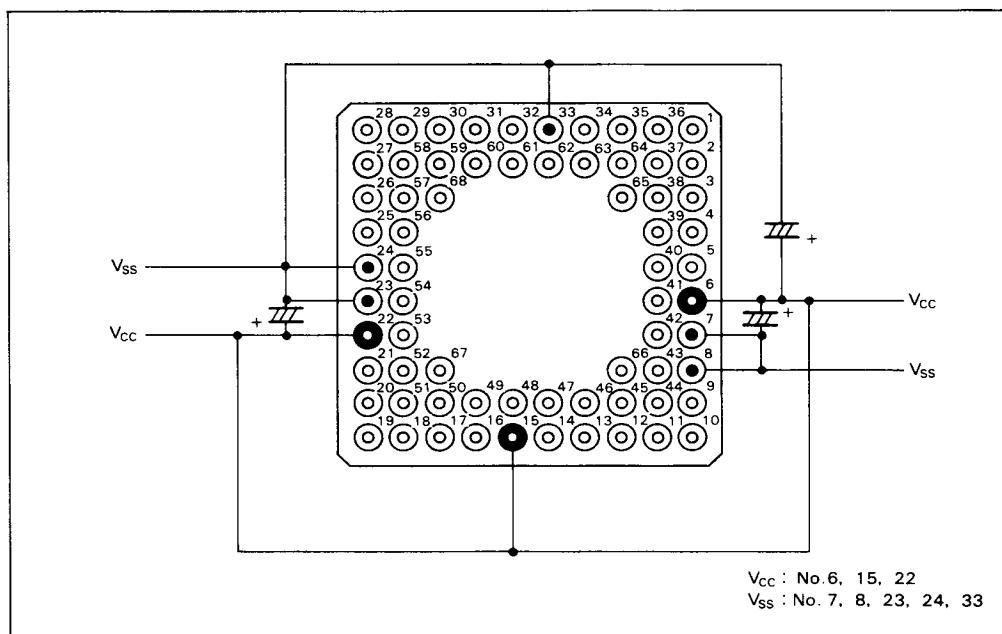

Figure 15. Power Supply Circuit Example 68-Pin PGA

Absolute Maximum Ratings

Item	Symbol	Rating	Unit
Supply Voltage	V_{cc} (Note 1)	-0.3 to +7.0	V
Input Voltage	V_{in} (Note 1)	-0.3 to $V_{cc} + 0.3$	V
Allowable Output Current	$ I_{Oj} $ (Note 2)	5	mA
Total Allowable Output Current	$ \Sigma I_O $ (Note 3)	120	mA
Operating Temperature	T_{opr}	0 to +70	°C
Storage Temperature	T_{stg}	-55 to +150	°C

- Notes:
1. Referenced to $V_{ss} = 0$ V.
 2. The maximum current that may be drawn from, or flow out of, one output, or one common input/output terminal.
 3. The total sum of currents that may be drawn from, or flow out of, all output or common input/output terminals.
 4. Using an LSI beyond its maximum rating may result in its permanent destruction.
LSIs should usually be used under recommended operating conditions. Exceeding any of these conditions may adversely affect reliability.

Recommended Operating Conditions

Item	Symbol	Min	Typ	Max	Unit

245

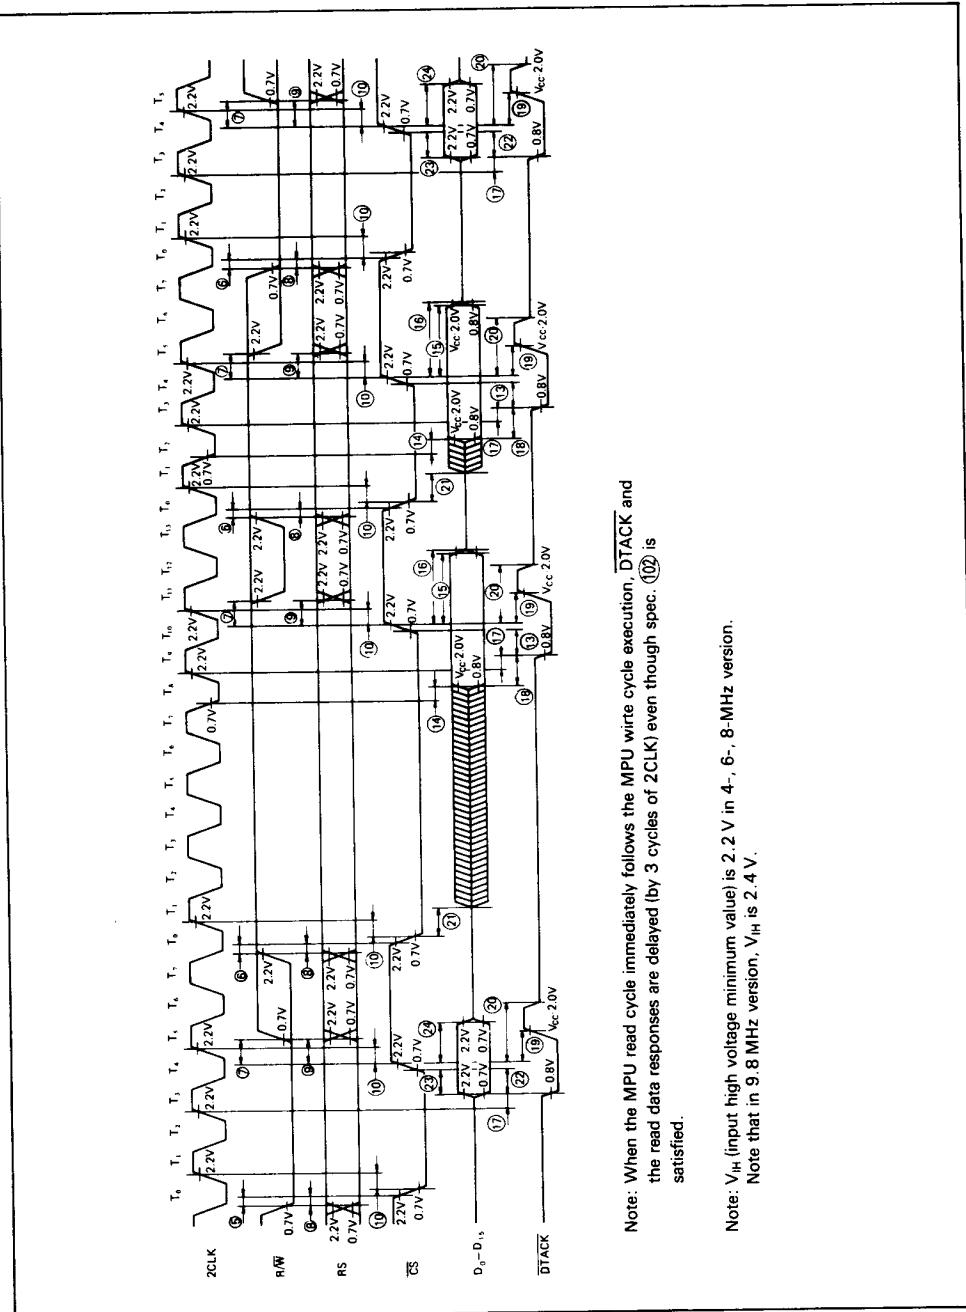

- Notes: 1. CS high width must satisfy the specification (1).
Unless spec. (12) is satisfied, DTACK response to the successence to the succeeding cycle is delayed.
2. When the ACRTC is used with the synchronous bus timing, the specifications (10), (11) and (12) must be satisfied.
- Note: V_{ih} (input high voltage minimum value) is 2.2 V in 4-, 6-, 8-MHz version.
Note that in 9.8 MHz version, V_{ih} is 2.4 V.

Figure 19. MPU Write Cycle Timing (MPU → ACRTC)

HITACHI

246 Hitachi America, Ltd. • Hitachi Plaza • 2000 Sierra Point Pkwy. • Brisbane, CA 94005-1819 • (415) 589-8300

Note: When the MPU read cycle immediately follows the MPU write cycle execution, DTACK and the read data responses are delayed (by 3 cycles of 2CLK) even though spec. (12) is satisfied.

Note: V_H (input high voltage minimum value) is 2.2 V in 4-, 6-, 8-MHz version.

Note that in 9.8 MHz version, V_H is 2.4 V.

Figure 20. MPU Read/Write Cycle Timing (MPU → ACRTC)

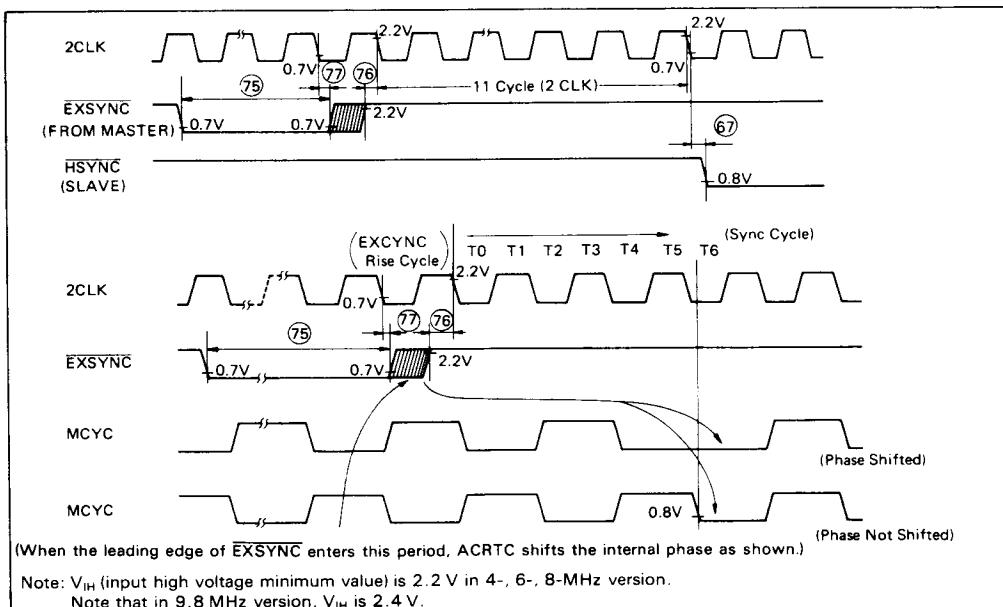

Figure 30. EXSYNC Input Timing

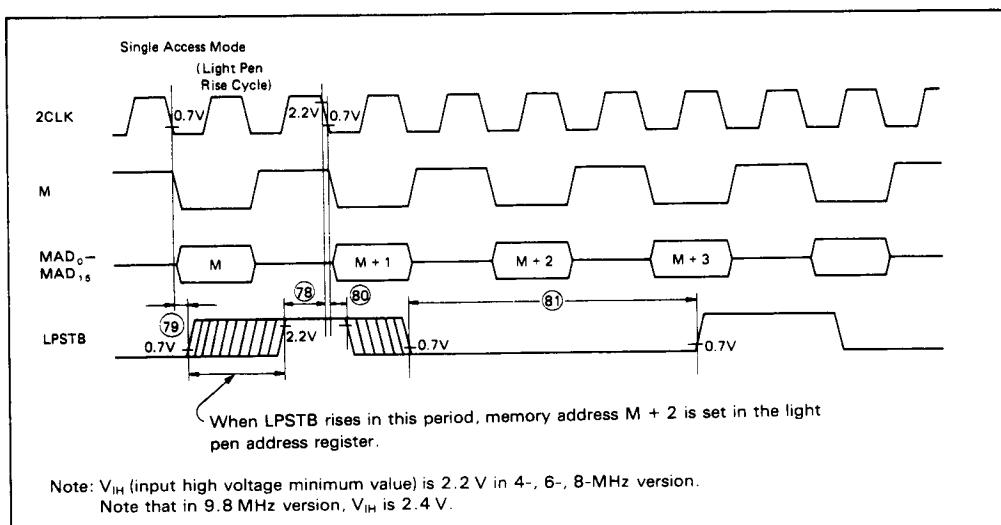

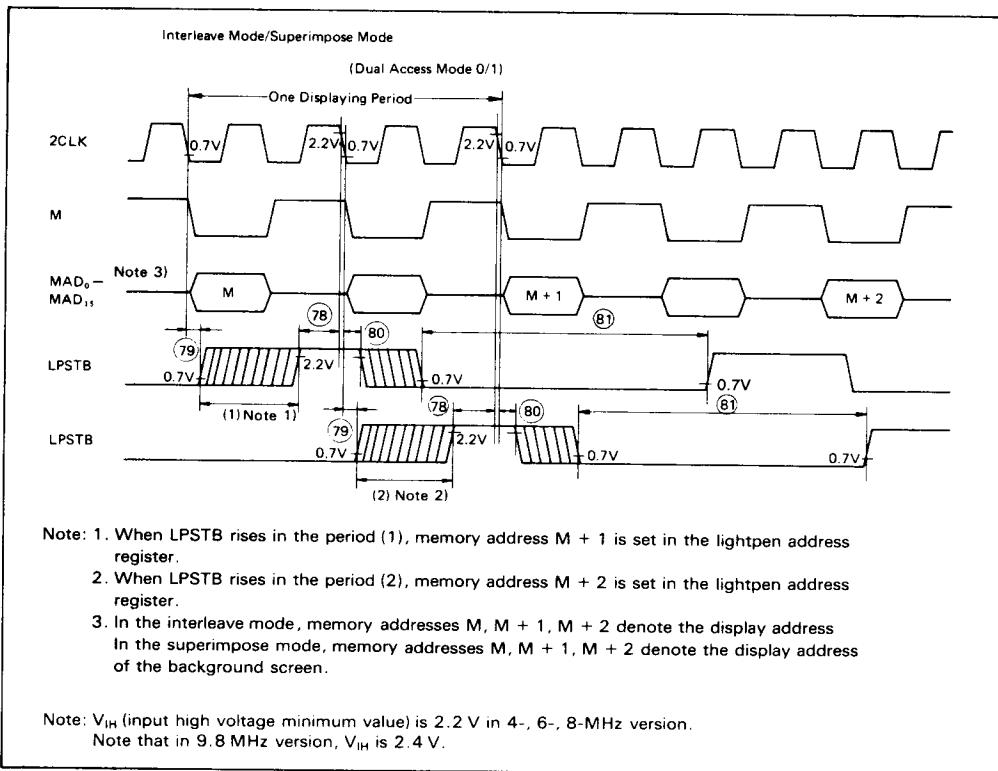

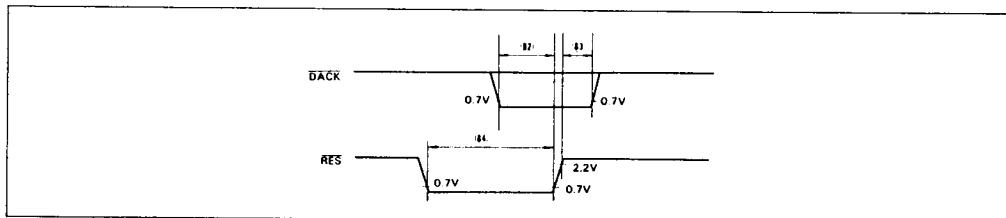

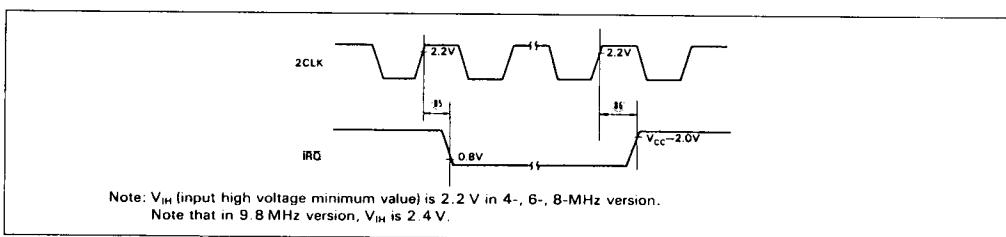

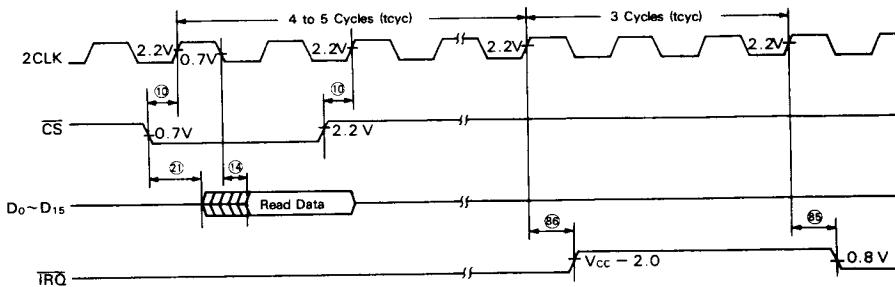

Figure 31. LPSTB Input Timing (Single Access Mode)

**Figure 32. LPSTB Input Timing (Dual Access Mode)****Figure 33. RES Input and DACK Input Timing (System Reset and 16-Bit/8-Bit Selection)****Figure 34. IRQ Output Timing**

This is an IRQ output timing example. In this case, IRQ is generated by status flag RFF (Read FIFO Full).

When issuing read commands (RD) which transfer data exceeding Read FIFO space (8 words), the FIFO becomes full, and the command execution pauses (RFF: set, IRQ: generated). By reading out 1-word data, spare occurs in the FIFO, and the ACRTC resets RFF flag and then negates IRQ, while on the other hand the ACRTC resumes the internal operation (command execution) to fill the FIFO, and sets RFF flag and then asserts IRQ again.

In this case, the timing from IRQ negate to assert is 3 cycles (tcyc).

Note: V_{IH} (input high voltage minimum value) is 2.2 V in 4-, 6-, 8-MHz version.

Note that in 9.8 MHz version, V_{IH} is 2.4 V.
