## Very Low Supply Current 3-Pin Microprocessor Reset Monitors

The MAX809 and MAX810 are cost-effective system supervisor circuits designed to monitor  $V_{CC}$  in digital systems and provide a reset signal to the host processor when necessary. No external components are required.

The reset output is driven active within 10  $\mu$ sec of  $V_{CC}$  falling through the reset voltage threshold. Reset is maintained active for a minimum of 140 msec after  $V_{CC}$  rises above the reset threshold. The MAX810 has an active-high RESET output while the MAX809 has an active-low  $\overline{\text{RESET}}$  output. The output of the MAX809 is guaranteed valid down to  $V_{CC} = 1.0$  V. Both devices are available in a SOT-23 package.

The MAX809/810 are optimized to reject fast transient glitches on the  $V_{CC}$  line. Low supply current of 1.0  $\mu$ A ( $V_{CC} = 3.2$  V) makes these devices suitable for battery powered applications.

### Features

- Precision  $V_{CC}$  Monitor for 2.5 V, 3.0 V, 3.3 V, and 5.0 V Supplies
- Precision Monitoring Voltages from 1.6 V to 4.9 V Available in 100 mV Steps
- 140 msec Guaranteed Minimum  $\overline{\text{RESET}}$  Output Duration
- $\overline{\text{RESET}}$  Output Guaranteed to  $V_{CC} = 1.0$  V
- Low Supply Current
- $V_{CC}$  Transient Immunity
- Small SOT-23 Package
- No External Components
- Wide Operating Temperature:  $-40^{\circ}\text{C}$  to  $105^{\circ}\text{C}$

### Typical Applications

- Computers
- Embedded Systems
- Battery Powered Equipment
- Critical  $\mu$ P Power Supply Monitoring

## APPLICATIONS INFORMATION

### V<sub>CC</sub> Transient Rejection

The MAX809 provides accurate V<sub>CC</sub> monitoring and reset timing during power-up, power-down, and brownout/sag conditions, and rejects negative-going transients (glitches) on the power supply line. Figure 2 shows the maximum transient duration vs. maximum negative excursion (overdrive) for glitch rejection. Any combination of duration and overdrive which lies **under** the curve will **not** generate a reset signal. Combinations above the curve are detected as a brownout or power-down. Typically, transient that goes 100 mV below the reset threshold and lasts 5 μs or less will not cause a reset pulse. Transient immunity can be improved by adding a capacitor in close proximity to the V<sub>CC</sub> pin of the MAX809.

**Figure 2. Maximum Transient Duration vs. Overdrive for Glitch Rejection at 25°C**

### RESET Signal Integrity During Power-Down

The MAX809  $\overline{\text{RESET}}$  output is valid to V<sub>CC</sub> = 1.0 V. Below this voltage the output becomes an “open circuit” and does not sink current. This means CMOS logic inputs to the μP will be floating at an undetermined voltage. Most digital systems are completely shutdown well above this voltage. However, in situations where  $\overline{\text{RESET}}$  must be maintained

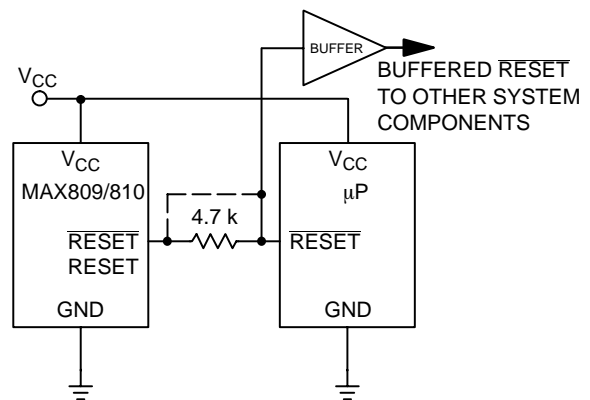

valid to V<sub>CC</sub> = 0 V, a pull-down resistor must be connected from  $\overline{\text{RESET}}$  to ground to discharge stray capacitances and hold the output low (Figure 3). This resistor value, though not critical, should be chosen such that it does not appreciably load  $\overline{\text{RESET}}$  under normal operation (100 kΩ will be suitable for most applications).

**Figure 3. Ensuring RESET Valid to V<sub>CC</sub> = 0 V**

### Processors With Bidirectional I/O Pins

Some μP's (such as Motorola 68HC11) have bi-directional reset pins. Depending on the current drive capability of the processor pin, an indeterminate logic level may result if there is a logic conflict. This can be avoided by adding a 4.7 kΩ resistor in series with the output of the MAX809 (Figure 4). If there are other components in the system which require a reset signal, they should be buffered so as not to load the reset line. If the other components are required to follow the reset I/O of the μP, the buffer should be connected as shown with the solid line.
