

FEATURES

- No Adjustments Required, Total Error ± 1 LSB Max Over Temperature
- Four Voltage-Output DACs on a Single Chip
- Internal 10V bandgap Reference
- Operates from Single +15V Supply
- Fast 50ns Data Load Time, All Temperatures
- Pin-for-Pin Replacement for PM-7226 and AD7226, Eliminates External Reference

APPLICATIONS

- Process Controls
- Multi-Channel Microprocessor Controlled:
 - System Calibration
 - Op Amp Offset and Gain Adjust
 - Level and Threshold Setting

GENERAL DESCRIPTION

The DAC-8426 is a complete quad voltage output D/A converter with internal reference. This product fits directly into any existing 7226 socket where the user currently has a 10V external reference. The external reference is no longer necessary. The internal reference of the DAC-8426 is laser-trimmed to $\pm 0.4\%$ offering a 25ppm/ $^{\circ}\text{C}$ temperature coefficient and 5mA of external load driving capability.

The DAC-8426 contains four 8-bit voltage-output CMOS D/A converters on a single chip. A 10V output bandgap reference sets the output full-scale voltage. The circuit also includes four input latches and interface control logic.

One of the four latches, selected by the address inputs, is loaded from the 8-bit data bus input when the write strobe is active low. All digital inputs are TTL/CMOS (5V) compatible. The on-board amplifiers can drive up to 10mA from either a single or dual supply. The on-board reference that is always connected to the internal DACs has 5mA available to drive external devices.

SIMPLIFIED SCHEMATIC

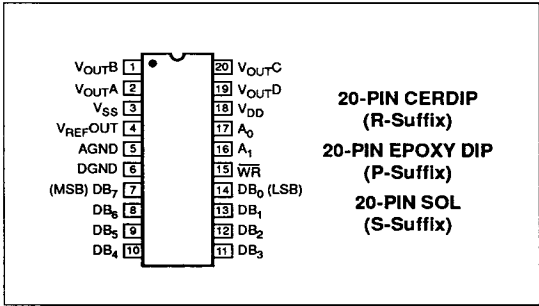

DAC-8426

GENERAL DESCRIPTION *Continued*

Its compact size, low power, and economical cost-per-channel, make the DAC-8426 attractive for applications requiring multiple D/A converters without sacrificing circuit-board space. System reliability is also increased due to reduced parts count.

PMI's advanced oxide-based, silicon-gate, CMOS process allows the DAC-8426's analog and digital circuitry to be manufactured on the same chip. This, coupled with PMI's highly stable thin-film R-2R resistor ladder, aids in matching and temperature tracking between DACs.

PIN CONNECTIONS

ABSOLUTE MAXIMUM RATINGS

V_{DD} to AGND or DGND	-0.3V, +17V
V_{SS} to AGND or DGND	-7V, V_{DD}

THERMAL RESISTANCE

PACKAGE TYPE	θ_{JA} (Note 2)	θ_{JC}	UNITS
20-Pin CerDIP (R)	70	7	°C/W
20-Pin Plastic DIP (P)	61	24	°C/W
20-Pin SOL (S)	80	22	°C/W

NOTES:

- Outputs may be shorted to any terminal provided the package power dissipation is not exceeded. Typical output short-circuit current to AGND is 50mA.
- θ_{JA} is specified for worst case mounting conditions, i.e., θ_{JA} is specified for device in socket for CerDIP and P-DIP packages; θ_{JA} is specified for device soldered to printed circuit board for SOL package.
- CAUTION:
- Do not apply voltages higher than V_{DD} or less than V_{SS} potential on any terminal.
- The digital control inputs are zener-protected; however, permanent damage may occur on unprotected units from high-energy electrostatic fields. Keep units in conductive foam at all times until ready to use.
- Do not insert this device into powered sockets. Remove power before insertion or removal.
- Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to device.

TYPICAL PERFORMANCE CHARACTERISTICS *Continued*

DAC-8426

PARAMETER DEFINITIONS

TOTAL UNADJUSTED ERROR (TUE)

This specification includes the Full-Scale-Error, Relative Accuracy Zero-Code-Error and the internal reference voltage. The ideal Full-Scale output voltage is 10V minus 1 LSB which equals 9.961 volts. Each LSB equals $10V \times (1/256) = 0.039$ volts.

DIGITAL CROSSTALK

Digital crosstalk is the signal coupled to the output of a DAC due to a changing digital input from adjacent DACs being updated. It is specified in nano-Volt-seconds(nVs).

Refer to the beginning of the Digital-to-Analog Converter section in the PMI databook for additional parameter definitions.

CIRCUIT DESCRIPTION

The DAC-8426 is a complete quad 8-bit D/A converter. It contains an internal bandgap reference, four voltage switched R-2R ladder DACs, four DAC latches, four output buffer amplifiers, and an address decoder. All four DACs share the internal ten volt reference and analog ground(AGND). Figure 1 provides an equivalent DAC plus buffer schematic.

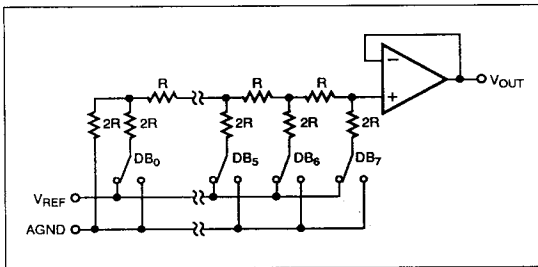

FIGURE 1: Simplified circuit configuration for one DAC. (Switches are shown for all "1s" on the digital inputs.)

The eleven digital inputs are compatible with both TTL and 5V(or higher) CMOS logic. Table 1 shows the DAC control logic truth table for \overline{WR} , A_1 , and A_0 operation. When \overline{WR} is active low the input latch of the selected DAC is transparent, and the DAC's output responds to the data present on the eight digital data inputs(DBx). The data (DBx) is latched into the addressed DAC's latch on the positive edge of the \overline{WR} control signal. The important timing requirements are shown in the Write Cycle Timing Diagram, Figure 2.

INTERNAL TEN VOLT REFERENCE

The internal 10V bandgap reference of the DAC-8426 is trimmed to the output voltage and temperature drift specifications. This internal reference is connected to the reference inputs of the four internal 8-bit D/A converters. The output terminal of the internal 10V reference is available on pin 4. The 10V output of the reference is produced with respect to the AGND pin. This reference output can be used to supply as much as 5mA of additional current to external devices. Care has been

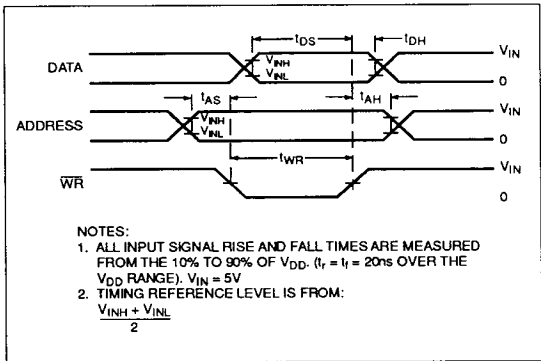

FIGURE 2: Write Cycle Timing Diagram

taken in the design of the internal DAC switching to minimize transients on the reference voltage terminal(V_{REF} OUT). Other devices connected to this reference terminal should have well behaved input loading characteristics. D/A converters such as the PMI PM-7226A have been designed to minimize reference input transient currents and can be directly connected to the DAC-8426 10V reference. Devices exhibiting large current transients due to internal switching should be buffered with an op amp to maintain good overall system noise performance. A 10 μ F reference output bypass capacitor is required.

BUFFER AMPLIFIER SECTION

The four internal unity-gain voltage buffers provide low output impedance capable of sourcing 5mA or sinking 350 μ A. Typical output slew rates of $\pm 4V/\mu s$ are achieved with 10V full-scale output changes and $R_L = 2k\Omega$. Figure 3 photographs show large-signal and settling time response. Capacitive loads to 3300pF maximum, and resistive loads to 2k Ω minimum can be applied.

FIGURE 3: Dynamic Response

The outputs can withstand an indefinite short-circuit to AGND to typically 50mA. The output may also be shorted to any voltage between V_{DD} and V_{SS} ; however, care must be taken to not exceed the device maximum power dissipation.

The amplifier's emitter follower output stage consists of an intrinsic NPN bipolar transistor with a 400 μ A NMOS pull-down current-source load connected to V_{SS} . This circuit configuration shown in Figure 4 enables the output amplifier to develop output voltages very close to AGND. Only the negative supply of the

four output buffer amplifiers are connected to V_{SS} . Operating the DAC-8426 from dual supplies ($V_{DD} = +15V$ and $V_{SS} = -5V$) improves negative going output settling time near zero volts.

When operating single supply ($V_{DD} = +15V$ and $V_{SS} = 0V$) the output sink current decreases as the output approaches zero voltage. Within 200mV of AGND (single-supply operation) the internal sinking capability appears resistive at a value of approximately 1200 Ω . The buffer amplifier output current and voltage characteristics are plotted in Figure 5.

DAC-8426

APPLICATIONS SETUP

UNIPOLAR OUTPUT OPERATION

The output voltage appearing at any output V_{OUT} is equal to the internal 10V reference multiplied by the decimal value of the latched digital input divided by 2^8 (=256). In equation form:

$$V_{OUT}(D) = D / 256 \times 10V$$

where $D = 0_{10}$ to 255_{10}

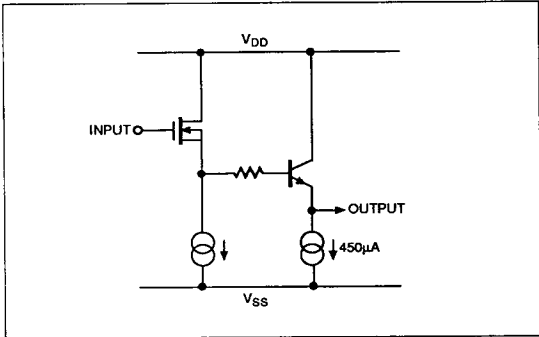

FIGURE 4: Amplifier Output Stage

Note that the maximum possible output is 1 LSB less than the internal 10V reference, that is, $255/256 \times 10V = 9.961V$. Table 2 lists output voltages for a given digital input. The total unadjusted error (TUE) specification of the product grade used determines the output tolerances of the values listed in Table 2. For example, a ± 2 LSB grade DAC-8426FP loaded with decimal 128_{10} (half-scale) would have a guaranteed output voltage occurring in the range of $5V \pm 2$ LSB, which is $5V \pm (2 \times 10V/256)$

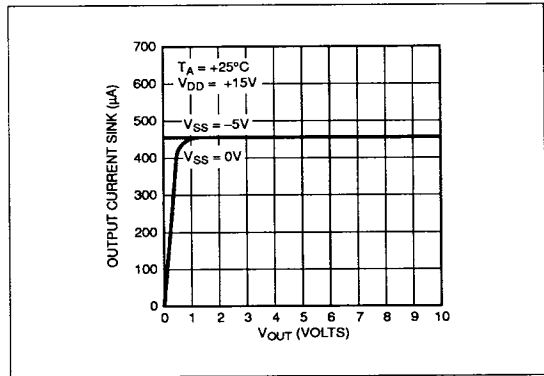

FIGURE 5: DAC Output Current Sink

$= 5V \pm 0.078V$. Therefore V_{OUT} is guaranteed to occur in the following range:

$$4.922V \leq V_{OUT}(128_{10}) \leq 5.078V$$

For the top grade DAC-8426EP ± 1 LSB total unadjusted error (TUE), the guaranteed range is $4.961V \leq V_{OUT}(128_{10}) \leq 5.039V$. These tolerances provide the worst case analysis including temperature changes.

One additional characteristic guaranteed is a DNL of ± 1 LSB on all grades. The DAC-8426 is therefore guaranteed to be monotonic. In the situation where a continuously positive 1 LSB digital increment is applied, the output voltage will always increase in value, never decrease. This is very important in servo applications and other closed-loop feedback systems. Finally, in the typical characteristic curves, long term output voltage drift (stability) is provided.

BIPOLAR OUTPUT OPERATION

An external op amp plus two resistors can easily convert any DAC output to bipolar output voltage swings. Figure 6 shows all four DACs output operating in bipolar mode. This is the general expression describing the bipolar output transfer equation:

$$V_{OUT}(D) = [(1+R_2/R_1) \times D/256 \times 10V] - R_2/R_1 \times 10V,$$

where $D = 0_{10}$ to 255_{10}

If $R_1 = R_2$, then V_{OUT} becomes:

$$V_{OUT}(D) = (D/128 - 1) \times 10V$$

Table 3 lists various output voltages with $R_1 = R_2$ versus digital input code. This coding is considered offset binary. Note that the LSB step size is now $20V/256 = 0.078V$, twice as large as the unipolar output case previously discussed. In order to minimize gain and offset errors, choose R_1 and R_2 to match and track within 0.1% over the selected operating temperature range of interest.

TABLE 2: Unipolar Output Voltage as a Function of Digital Input Code.

DIGITAL INPUT CODE	ANALOG OUTPUT VOLTAGE (= D/256 x 10V)	
255	9.961V	Full-Scale (FS)
254	9.922V	FS-1 LSB
129	5.039V	
128	5.000V	Half-Scale
127	4.961V	
1	0.039V	1 LSB
0	0.000V	Zero-Scale

OFFSETTING AGND

Since the DAC ladder and bandgap reference are terminated at AGND, it is possible to offset AGND positive with respect to DGND. The 10V output span remains if a positive offset is applied to AGND. The offset voltage source connected to AGND must be capable of sinking 14mA. AGND cannot be taken

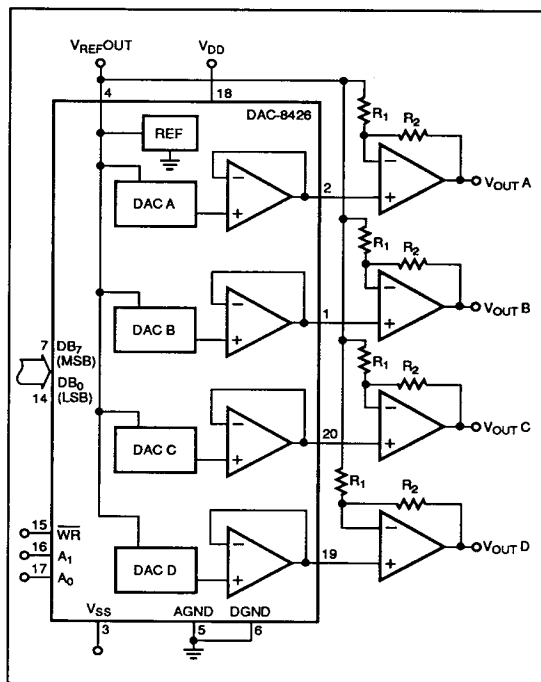

FIGURE 6: Bipolar Operation

negative with respect to DGND; this would forward bias an internal diode. Allowance must be made at V_{DD} to maintain 3.5V of headroom above $V_{REF-OUT}$. This connection setup is useful in single supply applications where virtual ground needs to be slightly positive with respect to ground. In this application connect V_{SS} to DGND to take advantage of the extra buffer output current sinking capability when the DAC output is programmed to all zeros code, see Figure 7.

CONNECTION AND LAYOUT GUIDELINES

Layout and design techniques used in the interface between digital and analog circuitry require special attention to detail. The following considerations should be evaluated prior to PCB layout.

1. Return signal paths through the ground system should be carefully considered. High-speed digital logic current pulses traveling on return ground traces generate glitches that can be radiated to the analog circuits if the ground path layout produces loop antennas. Ground planes can minimize this situation. Separate digital and analog grounding areas to minimize crosstalk. Ideally a single common-point ground should be on the same PCB board as the DAC-8426. The analog ground returns should take advantage of the appropriate placement of power supply bypass capacitors.

TABLE 3: Bipolar Output Voltage as a Function of Digital Input Code

DIGITAL INPUT CODE	ANALOG OUTPUT VOLTAGE (= D/256 x 10V)	
255	9.922V	Full-Scale (FS)
254	9.844V	FS-1 LSB
129	0.078V	Zero-Scale
128	0.000V	
127	-0.078V	Neg Full-Scale
1	-9.922V	
0	-10.000V	

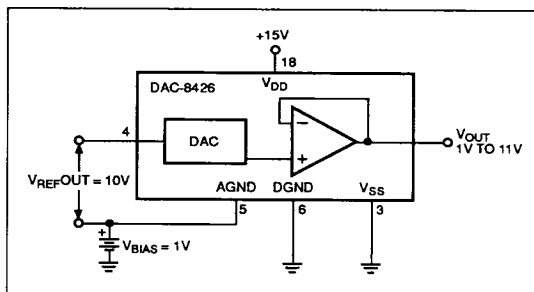

FIGURE 7: AGND Biasing Scheme Providing Offset Output Range

2. For optimum performance, bypass V_{DD} and V_{SS} (if using negative supply voltage) with 0.1μF ceramic disk capacitors to shunt high-frequency spikes. Also use in parallel 6.8μ to 10μF capacitors to provide a charge reservoir for lower frequency load change requirements. The reference output ($V_{REF-OUT}$) should be bypassed with a 10μF tantalum capacitor to optimize reference output stability during data input changes. This helps to minimize digital crosstalk.
3. Power Supply Sequencing — No special requirements exist with the DAC-8426. However, users should be aware that often the 5V logic supply may be powered up momentarily prior to the +15V analog supply. In this situation, the DAC-8426 ESD input protection diodes will forward bias if the applied input logic is at logic "1". No damage will result to the input since the DAC-8426 is designed to withstand momentary currents of up to 130mA. This situation will likely exist for any DAC or ADC operating from a separate analog supply.
4. ESD input protection — Attention has been given in the design of the DAC-8426 to ESD sensitivity. Using the human body model test technique (MIL-STD 3015.4) the DAC-8426 generally will withstand 1500V ESD transients on all pins. Handling and testing prior to PCB insertion generally exposes ICs to the toughest environment they will experience. Once the IC is soldered in the PCB, it is still important to consider any traces that connect to PCB edge connectors. These traces should be protected with appropriate devices

DAC-8426

especially if the boards will experience field replacement or adjustment. Handling the exposed edge connectors by field maintenance people in a low humidity environment can produce 20kV ESD transients which will be detrimental to almost any integrated IC connected to the edge connector.

MICROPROCESSOR INTERFACING

The DAC-8426 easily interfaces to most 8- and 16-bit wide databus systems. Serial and 4-bit busses can also be accommodated with additional latches and control circuitry. Interfacing can be accomplished with data bus transfers running with 50ns write pulse widths.

Examples of various microprocessor interface circuits are provided in Figures 8 through 12. These figures have omitted circuitry not essential to the bus interface. The design process should include review of the DAC-8426 timing diagram with the μP system timing diagram.
