Max. Column Address Access Time, (t_{CAA})	25 ns	30 ns	35 ns
Min. Extended Data Out Page Mode Cycle Time, (t_{PC})	20 ns	25 ns	30 ns
Min. Read/Write Cycle Time, (t_{RC})	84 ns	104 ns	124 ns

Features

- 1M x 16-bit organization
- EDO Page Mode for a sustained data rate of 50 MHz
- $\overline{\text{RAS}}$ access time: 50, 60, 70 ns
- Dual $\overline{\text{CAS}}$ Inputs
- Low power dissipation
- Read-Modify-Write, $\overline{\text{RAS}}$ -Only Refresh, $\overline{\text{CAS}}$ -Before- $\overline{\text{RAS}}$ Refresh, Hidden Refresh, and Self Refresh.
- Refresh Interval: 1024 cycles/16 ms
- Available in 42-pin 400 mil SOJ and 50/44-pin 400 mil TSOP-II
- Single +3.3 V ± 0.3 V Power Supply
- TTL Interface

Description

The V53C318165A is a 1048576 x 16 bit high-performance CMOS dynamic random access memory. The V53C318165A offers Page mode operation with Extended Data Output. The V53C318165A has an symmetric address, 10-bit row and 10-bit column.

All inputs are TTL compatible. EDO Page Mode operation allows random access up to 1024 x 16 bits, within a page, with cycle times as short as 20ns.

These features make the V53C318165A ideally suited for a wide variety of high performance computer systems and peripheral applications.

Notes:

1. All voltage are referenced to V_{SS} .
2. I_{CC1} , I_{CC3} , I_{CC4} , and I_{CC7} depend on cycle rate.
3. I_{CC1} and I_{CC4} depend on output loading. Specified values are measured with the output open.
4. Address can be changed once or less while $\overline{RAS} = V_{IL}$. In the case of I_{CC4} it can be changed once or less during an EDO cycle (t_{HPC}).
5. An initial pause of 200 μs is required after power-up followed by 8 $\overline{RAS}$ cycles of which at least one cycle has to be a refresh cycle, before proper device operation is achieved. In case of using internal refresh counter, a minimum of 8 $\overline{CAS}$ -before- $\overline{RAS}$ initialization cycles instead of 8 $\overline{RAS}$ cycles are required.
6. V_{IH} (min.) and V_{IL} (max.) are reference levels for measuring timing of input signals. Transition times are also measured between V_{IH} and V_{IL} .
7. Measured with a load equivalent to 2 TTL gates and 50 pF ($V_{OL} = 0.8V$ and $V_{OH} = 2.0V$).
8. t_{OFF} (max.) and t_{OEZ} (max.) define the time at which the outputs achieve the open-circuit condition and are not referenced to output voltage levels.
9. Either t_{RCH} or t_{RRH} must be satisfied for a read cycle.
10. These parameters are referenced to the $\overline{CAS}$ leading edge in early write cycles and to the $\overline{WE}$ leading edge in read-write cycles.
11. t_{WCS} , t_{RWD} , t_{CWD} , t_{AWD} and t_{CPWD} are not restrictive operating parameters. They are included in the data sheet as electrical characteristics only. If $t_{WCS} > t_{WCS}(\text{min.})$, the cycle is an early write cycle and the I/O pin will remain open-circuit (high impedance) through the entire cycle; if $t_{RWD} > t_{RWD}(\text{min.})$, $t_{CWD} > t_{CWD}(\text{min.})$, $t_{AWD} > t_{AWD}(\text{min.})$, and $t_{CPWD} > t_{CPWD}(\text{min.})$, the cycle is a read-write cycle and I/O pins will contain data read from the selected cells. If neither of the above sets of conditions is satisfied, the condition of the I/O pins (at access time) is indeterminate.
12. Operation within the $t_{RCD}(\text{max.})$ limit ensures that $t_{RAC}(\text{max.})$ can be met. $t_{RCD}(\text{max.})$ is specified as a reference point only: if t_{RCD} is greater than the specified $t_{RCD}(\text{max.})$ limit, then access time is controlled by t_{CAC} .
13. Operation within the $t_{RAD}(\text{max.})$ limit ensures that $t_{RAC}(\text{max.})$ can be met. $t_{RAD}(\text{max.})$ is specified as a reference point only: if t_{RAD} is greater than the specified $t_{RAD}(\text{max.})$ limit, then access time is controlled by t_{CAA} .
14. AC measurements assume $t_f = 2 \text{ ns}$.
15. Either t_{DZC} or t_{DEO} must be satisfied.
16. Either t_{CDD} or t_{ODD} must be satisfied.
17. When using Self Refresh mode, the following refresh operations must be performed to ensure proper DRAM operation:

If row addresses are being refreshed on an evenly distributed manner over the refresh interval using CBR refresh cycles, then only one CBR cycle must be performed immediately after exit from Self Refresh.

If row addresses are being refreshed in any other manner (ROR – Distributed/Burst; or CBR – Burst) over the refresh interval, then a full set of row refreshes must be performed immediately before entry to and immediately after exit from Self Refresh.
18. t_{OFF} is referenced from the rising edge of $\overline{RAS}$ or $\overline{CAS}$, whichever occurs last.

[illegible]

The timing diagram illustrates the relationship between several control and data signals for the 311816500-0 device. The signals shown are $\overline{\text{RAS}}$, $\overline{\text{UCAS}}$, $\overline{\text{LCAS}}$, ADDRESS, $\overline{\text{WE}}$, $\overline{\text{OE}}$, and I/O. The diagram includes various timing parameters such as t_{AR} , t_{RAS} , t_{RC} , t_{RP} , t_{CRP} , t_{RCD} , t_{CSH} , t_{RSH} , t_{CAS} , t_{RAH} , t_{CAR} , t_{CAH} , t_{ASR} , t_{RAD} , t_{CWL} , t_{WP} , t_{WCR} , t_{RWL} , t_{DHR} , t_{DS} , and t_{DH} . The ADDRESS signal is shown with a hatched pattern for the ROW ADDRESS and COLUMN ADDRESS. The I/O signal is shown with a hatched pattern for the VALID DATA-IN period.

The timing diagram illustrates the relationship between several control and data signals for the 311816500 device. The signals and their timing parameters are as follows:

- RAS:** Row Address Strobe. Timing parameters include t_{AR} (access time), t_{AS} (setup time), t_{RCH} (hold time), and t_{RP} (pulse width).
- UCAS, LCAS:** Column Address Strobe (UCAS) and Column Address Strobe (LCAS). Timing parameters include t_{CRP} (setup time), t_{CD} (delay time), t_{PC} (pulse width), $t_{RSH(R)}$ (hold time), and t_{CRP} (pulse width).
- ADDRESS:** Row and Column Address. Timing parameters include t_{ASR} (setup time), t_{RAH} (hold time), t_{ASH} (setup time), t_{CAH} (hold time), and t_{RCH} (hold time).
- WE:** Write Enable. Timing parameters include t_{CAA} (setup time), t_{CAP} (pulse width), t_{CAA} (hold time), and t_{RRH} (hold time).
- OE:** Output Enable. Timing parameters include t_{OAC} (setup time), t_{OAC} (hold time), t_{OAC} (hold time), and t_{OAC} (hold time).
- I/O:** Data Input/Output. Timing parameters include t_{VOD} (setup time), t_{VOD} (hold time), t_{VOD} (hold time), and t_{VOD} (hold time).

The diagram shows the sequence of operations: RAS and UCAS/LCAS are active low pulses. ADDRESS is active low and contains row and column addresses. WE and OE are active low pulses. I/O is the data bus, showing valid data output during the active periods of the control signals.

The timing diagram illustrates the relationship between various control and data signals for the 311816500-1 device. The signals shown are:

- RAS**: Row Address Strobe, active low. Timing parameters include t_{AR} (access time), t_{RASP} (RAS pulse width), and t_{RP} (RAS to CAS delay).
- UCAS, LCAS**: Column Address Strobe and Local Column Address Strobe, active low. Timing parameters include t_{CRP} (column refresh period), t_{PC} (RAS to CAS delay), t_{CP} (CAS pulse width), t_{CAS} (CAS setup/hold time), t_{RSH} (RAS to SH), t_{CSH} (CAS to SH), t_{CAH} (CAS to AH), t_{CWL} (CAS to WL), t_{wCS} (CAS to WCH), t_{wP} (CAS to WTP), t_{DS} (data setup time), and t_{DH} (data hold time).
- ADDRESS**: Data bus address. Timing parameters include t_{RAH} (RAS to AH), t_{CAH} (CAS to AH), t_{CWL} (CAS to WL), t_{wCS} (CAS to WCH), t_{wP} (CAS to WTP), t_{DS} (data setup time), and t_{DH} (data hold time).
- WE**: Write Enable, active low. Timing parameters include t_{RAD} (RAS to AD), t_{CWL} (CAS to WL), t_{wCS} (CAS to WCH), t_{wP} (CAS to WTP), t_{DS} (data setup time), and t_{DH} (data hold time).
- OE**: Output Enable, active low. Timing parameters include t_{DS} (data setup time) and t_{DH} (data hold time).
- I/O**: Data bus input/output. Timing parameters include t_{DS} (data setup time) and t_{DH} (data hold time).

The diagram shows the timing of these signals relative to each other, with specific timing parameters labeled for each signal transition. The signals are shown as waveforms with high and low levels, and the timing parameters are indicated by arrows and labels.

10

The timing diagram illustrates the relationship between several control and data signals over time. The signals shown are:

- RAS**: Row Address Strobe, active low.
- UCAS, LCAS**: Column Address Strobe / Local Column Address Strobe, active low.
- ADDRESS**: Data bus address input, alternating between ROW ADDRESS and COLUMN ADDRESS.
- WE**: Write Enable, active low.
- OE**: Output Enable, active low.
- I/O**: Data bus output/input, showing OUT and IN cycles.

Key timing parameters defined in the diagram include:

- t_{RASP} : RAS pulse width.
- t_{CSH} , t_{CD} , t_{PCM} , t_{CP} , t_{CAS} , t_{CRP} , t_{RSH} : Various strobe and setup/hold times related to RAS and UCAS/LCAS.
- t_{RAD} , t_{RAH} , t_{ASR} , t_{ASC} , t_{CAH} : Setup and hold times for UCAS/LCAS relative to ADDRESS.
- t_{RCS} , t_{RWD} , t_{CWL} , t_{CWD} , t_{CPWD} , t_{RWL} , t_{CWL} : Timing parameters for WE pulses.
- t_{CAA} , t_{AWD} , t_{WPD} , t_{OAC} , t_{CAP} , t_{TODD} , t_{CAC} , t_{TRAC} , t_{OEZ} , t_{DH} , t_{PS} : Various setup, hold, and delay times for OE and I/O operations.
- t_{LZ} : Latency time from I/O enable to data valid.

311816500-1

The diagram illustrates the timing relationships for the 311816500-12 device. It shows the following signals and their timing parameters:

- RAS:** The RAS signal transitions from V_{IH} to V_{IL} . The total duration of the low pulse is t_{RC} . The time from the falling edge of RAS to the start of the data output is t_{RAS} . The time from the rising edge of RAS to the end of the data output is t_{RP} . The time from the rising edge of RAS to the start of the data output is t_{CRP} .
- UCAS, LCAS:** The UCAS and LCAS signals transition from V_{IH} to V_{IL} . The time from the falling edge of UCAS/LCAS to the start of the data output is t_{ASR} .
- ADDRESS:** The ADDRESS signal transitions from V_{IH} to V_{IL} . The time from the falling edge of ADDRESS to the start of the data output is t_{RAH} .
- I/O:** The I/O signal transitions from V_{OH} to V_{OL} . The time from the falling edge of I/O to the start of the data output is t_{RAH} .

Waveforms of Hidden Refresh Cycle (Read)**Waveforms of Hidden Refresh Cycle (Write)**

Waveforms of Self Refresh Cycle (optional)**Functional Description**

The V53C318165A is a CMOS dynamic RAM optimized for high data bandwidth, low power applications. It is functionally similar to a traditional dynamic RAM. The V53C318165A reads and writes data by multiplexing an 20-bit address into a 10-bit row and a 10-bit column address. The row address is latched by the Row Address Strobe ($\overline{\text{RAS}}$). The column address “flows through” an internal address buffer and is latched by the Column Address Strobe ($\overline{\text{CAS}}$). Because access time is primarily dependent on a valid column address rather than the precise time that the $\overline{\text{CAS}}$ edge occurs, the delay time from $\overline{\text{RAS}}$ to $\overline{\text{CAS}}$ has little effect on the access time.

Memory Cycle

A memory cycle is initiated by bringing $\overline{\text{RAS}}$ low. Any memory cycle, once initiated, must not be ended or aborted before the minimum t_{RAS} time has expired. This ensures proper device operation and data integrity. A new cycle must not be initiated until the minimum precharge time $t_{\text{RP}}/t_{\text{CP}}$ has elapsed.

Read Cycle

A Read cycle is performed by holding the Write Enable ($\overline{\text{WE}}$) signal High during a $\overline{\text{RAS}}$ / $\overline{\text{CAS}}$ operation. The column address must be held for a minimum specified by t_{AR} . Data Out becomes valid only when t_{OAC} , t_{RAC} , t_{CAA} and t_{CAC} are all satisfied. As a result, the access time is dependent on the timing relationships between these parameters. For example, the access time is limited by t_{CAA} when t_{RAC} , t_{CAC} and t_{OAC} are all satisfied.

Write Cycle

A Write Cycle is performed by taking $\overline{\text{WE}}$ and $\overline{\text{CAS}}$ low during a $\overline{\text{RAS}}$ operation. The column address is latched by $\overline{\text{CAS}}$. The Write Cycle can be $\overline{\text{WE}}$ controlled or $\overline{\text{CAS}}$ controlled depending on whether $\overline{\text{WE}}$ or $\overline{\text{CAS}}$ falls later. Consequently, the input data must be valid at or before the falling edge of $\overline{\text{WE}}$ or $\overline{\text{CAS}}$, whichever occurs last. In the $\overline{\text{CAS}}$ -controlled Write Cycle, when the leading edge of $\overline{\text{WE}}$ occurs prior to the $\overline{\text{CAS}}$ low transition, the I/O data pins will be in the High-Z state at the beginning of the Write function. Ending the Write with $\overline{\text{RAS}}$ or $\overline{\text{CAS}}$ will maintain the output in the High-Z state.

In the $\overline{\text{WE}}$ controlled Write Cycle, $\overline{\text{OE}}$ must be in the high state and t_{OED} must be satisfied.

Extended Data Output Page Mode

EDO Page operation permits all 1024 columns within a selected row of the device to be randomly accessed at a high data rate. Maintaining RAS low while performing successive CAS cycles retains the row address internally and eliminates the need to reapply it for each cycle. The column address buffer acts as a transparent or flow-through latch while CAS is high. Thus, access begins from the occurrence of a valid column address rather than from the falling edge of CAS, eliminating t_{ASC} and t_T from the critical timing path. CAS latches the address into the column address buffer. During EDO operation, Read, Write, Read-Modify-Write or Read-Write-Read cycles are possible at random addresses within a row. Following the initial entry cycle into EDO Mode, access is t_{CAA} or t_{CAP} controlled. If the column address is valid prior to the rising edge of CAS, the access time is referenced to the CAS rising edge and is specified by t_{CAP} . If the column address is valid after the rising CAS edge, access is timed from the occurrence of a valid address and is specified by t_{CAA} . In both cases, the falling edge of CAS latches the address and enables the output.

EDO provides a sustained data rate of 50 MHz for applications that require high bandwidth such as bit-mapped graphics or high-speed signal processing. The following equation can be used to calculate the maximum data rate:

$$\text{Data Rate} = \frac{1024}{t_{RC} + 1023 \times t_{PC}}$$

Self Refresh

Self Refresh mode provides internal refresh control signals to the DRAM during extended periods of inactivity. Device operation in this mode provides additional power savings and design ease by elimination of external refresh control signals. Self Refresh mode is initiated with a CAS before RAS (CBR) Refresh cycle, holding both RAS low (t_{RASS}) and CAS low (t_{CHD}) for a specified period. Both of these parameters are specified with minimum values to guarantee entry into Self Refresh operation. Once the device has been placed in to Self Refresh mode the CAS clock is no longer required to maintain Self Refresh operation.

The Self Refresh mode is terminated by returning the RAS clock to a high level for a specified (t_{RPS}) minimum time. After termination of the Self Refresh cycle normal accesses to the device may be initiated immediately, providing that subsequent refresh cycles utilize the CAS before RAS (CBR) mode of operation.

Data Output Operation

The V53C318165A Input/Output is controlled by OE, CAS, WE and RAS. A RAS low transition enables the transfer of data to and from the selected row address in the Memory Array. A RAS high transition disables data transfer and latches the output data if the output is enabled. After a memory cycle is initiated with a RAS low transition, a CAS low transition or CAS low level enables the internal I/O path. A CAS high transition or a CAS high level disables the I/O path and the output driver if it is enabled. A CAS low transition while RAS is high has no effect on the I/O data path or on the output drivers. The output drivers, when otherwise enabled, can be disabled by holding OE high. The OE signal has no effect on any data stored in the output latches. A WE low level can also disable the output drivers when CAS is low. During a Write cycle, if WE goes low at a time in relationship to CAS that would normally cause the outputs to be active, it is necessary to use OE to disable the output drivers prior to the WE low transition to allow Data In Setup Time (t_{DS}) to be satisfied.

Power-On

After application of the V_{CC} supply, an initial pause of 200 μs is required followed by a minimum of 8 initialization cycles (any combination of cycles containing a RAS clock). Eight initialization cycles are required after extended periods of bias without clocks (greater than the Refresh Interval).

During Power-On, the V_{CC} current requirement of the V53C318165A is dependent on the input levels of RAS and CAS. If RAS is low during Power-On, the device will go into an active cycle and I_{CC} will exhibit current transients. It is recommended that RAS and CAS track with V_{CC} or be held at a valid V_{IH} during Power-On to avoid current surges.

Table 1. V53C318165A Data Output
Operation for Various Cycle Types

Cycle Type	I/O State
Read Cycles	Data from Addressed Memory Cell
CAS-Controlled Write Cycle (Early Write)	High-Z
$\overline{WE}$ -Controlled Write Cycle (Late Write)	$\overline{OE}$ Controlled. High $\overline{OE}$ = High-Z I/Os
Read-Modify-Write Cycles	Data from Addressed Memory Cell
EDO Read Cycle	Data from Addressed Memory Cell
EDO Write Cycle (Early Write)	High-Z
EDO Read-Modify-Write Cycle	Data from Addressed Memory Cell
$\overline{RAS}$ -only Refresh	High-Z
$\overline{CAS}$ -before- $\overline{RAS}$ Refresh Cycle	High-Z
$\overline{CAS}$ -only Cycles	High-Z
