# High-Speed, Single-Supply, Rail-to-Rail OPERATIONAL AMPLIFIERS MicroAmplifier ${ }^{\text {T" }}$ Series 

## FEATURES

- RAIL-TO-RAIL INPUT
- RAIL-TO-RAIL OUTPUT (within 10mV)
- WIDE BANDWIDTH: 38MHz
- HIGH SLEW RATE: 22V/ $\mu \mathrm{s}$
- LOW NOISE: $5 \mathrm{nV} / \sqrt{\mathrm{Hz}}$
- LOW THD+NOISE: 0.0006\%
- UNITY-GAIN STABLE
- MicroSIZE PACKAGES
- SINGLE, DUAL, AND QUAD

DESCRIPTION
OPA350 series rail-to-rail CMOS operational amplifiers are optimized for low voltage, single-supply operation. Rail-to-rail input/output, low noise ( $5 \mathrm{nV} / \mathrm{HHz}$ ), and high speed operation ( $38 \mathrm{MHz}, 22 \mathrm{~V} / \mu \mathrm{s}$ ) make them ideal for driving sampling analog-to-digital converters. They are also well suited for cell phone PA control loops and video processing ( $75 \Omega$ drive capability) as well as audio and general purpose applications. Single, dual, and quad versions have identical specifications for maximum design flexibility.
The OPA350 series operates on a single supply as low as 2.5 V with an input common-mode voltage range that

## APPLICATIONS <br> - CELL PHONE PA CONTROL LOOPS <br> - DRIVING A/D CONVERTERS <br> - VIDEO PROCESSING <br> - DATA ACQUISITION <br> - PROCESS CONTROL <br> - AUDIO PROCESSING <br> - COMMUNICATIONS <br> - ACTIVE FILTERS <br> - TEST EQUIPMENT

extends 300 mV below ground and 300 mV above the positive supply. Output voltage swing is to within 10 mV of the supply rails with a $10 \mathrm{k} \Omega$ load. Dual and quad designs feature completely independent circuitry for lowest crosstalk and freedom from interaction.
The single (OPA350) and dual (OPA2350) come in the miniature MSOP-8 surface mount, SO-8 surface mount, and 8-pin DIP packages. The quad (OPA4350) packages are the space-saving SSOP-16 surface mount and SO-14 surface mount. All are specified from $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ and operate from $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$.

|  |  |
| Output Short Circuit ${ }^{(3)}$ | Continuous |
| Operating Temperature | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Storage Temperature | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Junction Temperature | $150^{\circ} \mathrm{C}$ |
| Lead Temperature (solde | $300^{\circ} \mathrm{C}$ |

NOTES: (1) Stresses above these ratings may cause permanent damage. Exposure to absolute maximum conditions for extended periods may degrade device reliability. (2) Input terminals are diode-clamped to the power supply rails. Input signals that can swing more than 0.3 V beyond the supply rails should be current-limited to 10 mA or less. (3) Short circuit to ground, one amplifier per package.

## ELECTROSTATIC DISCHARGE SENSITIVITY

This integrated circuit can be damaged by ESD. Burr-Brown recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.
ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

## APPLICATIONS INFORMATION

OPA350 series op amps are fabricated on a state-of-the-art 0.6 micron CMOS process. They are unity-gain stable and suitable for a wide range of general purpose applications. Rail-to-rail input/output make them ideal for driving sampling A/D converters. They are also well suited for controlling the output power in cell phones. These applications often require high speed and low noise. In addition, the OPA350 series offers a low cost solution for general purpose and consumer video applications ( $75 \Omega$ drive capability).
Excellent ac performance makes the OPA350 series well suited for audio applications. Their bandwidth, slew rate, low noise $(5 \mathrm{nV} / \sqrt{\mathrm{Hz}})$, low THD $(0.0006 \%)$, and small package options are ideal for these applications. The class AB output stage is capable of driving $600 \Omega$ loads connected to any point between $\mathrm{V}+$ and ground.
Rail-to-rail input and output swing significantly increases dynamic range, especially in low voltage supply applications. Figure 1 shows the input and output waveforms for

FIGURE 1. Rail-to-Rail Input and Output.
the OPA350 in unity-gain configuration. Operation is from a single +5 V supply with a $1 \mathrm{k} \Omega$ load connected to $\mathrm{V}_{\mathrm{S}} / 2$. The input is a $5 \mathrm{Vp}-\mathrm{p}$ sinusoid. Output voltage swing is approximately $4.95 \mathrm{Vp}-\mathrm{p}$.

Power supply pins should be bypassed with $0.01 \mu \mathrm{~F}$ ceramic capacitors.

## OPERATING VOLTAGE

OPA350 series op amps are fully specified from +2.7 V to +5.5 V . However, supply voltage may range from +2.5 V to +5.5 V . Parameters are guaranteed over the specified supply range-a unique feature of the OPA350 series. In addition, many specifications apply from $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$. Most behavior remains virtually unchanged throughout the full operating voltage range. Parameters which vary significantly with operating voltage or temperature are shown in the typical performance curves.

## RAIL-TO-RAIL INPUT

The guaranteed input common-mode voltage range of the OPA350 series extends 100 mV beyond the supply rails. This is achieved with a complementary input stage-an N -channel input differential pair in parallel with a P-channel differential pair (see Figure 2). The N-channel pair is active for input voltages close to the positive rail, typically $(\mathrm{V}+)-1.8 \mathrm{~V}$ to 100 mV above the positive supply, while the P-channel pair is on for inputs from 100 mV below the negative supply to approximately $(\mathrm{V}+)-1.8 \mathrm{~V}$. There is a small transition region, typically $(\mathrm{V}+)-2 \mathrm{~V}$ to $(\mathrm{V}+)-1.6 \mathrm{~V}$, in which both pairs are on. This 400 mV transition region can vary $\pm 400 \mathrm{mV}$ with process variation. Thus, the transition region (both input stages on) can range from $(\mathrm{V}+)-2.4 \mathrm{~V}$ to $(\mathrm{V}+)-2.0 \mathrm{~V}$ on the low end, up to $(\mathrm{V}+)-1.6 \mathrm{~V}$ to $(\mathrm{V}+)-1.2 \mathrm{~V}$ on the high end.

FIGURE 2. Simplified Schematic.

OPA350 series op amps are laser-trimmed to reduce offset voltage difference between the N -channel and P-channel input stages, resulting in improved commonmode rejection and a smooth transition between the N -channel pair and the P-channel pair. However, within the 400 mV transition region PSRR, CMRR, offset voltage, offset drift, and THD may be degraded compared to operation outside this region.

A double-folded cascode adds the signal from the two input pairs and presents a differential signal to the class AB output stage. Normally, input bias current is approximately 500fA. However, large inputs (greater than 300 mV beyond the supply rails) can turn on the OPA350's input protection diodes, causing excessive current to flow in or out of the input pins. Momentary voltages greater than 300 mV beyond the power supply can be tolerated if the current on the input pins is limited to 10 mA . This is easily accomplished with an input resistor as shown in Figure 3. Many input signals are inherently current-limited to less than 10 mA , therefore, a limiting resistor is not required.

FIGURE 3. Input Current Protection for Voltages Exceeding the Supply Voltage.

## RAIL-TO-RAIL OUTPUT

A class AB output stage with common-source transistors is used to achieve rail-to-rail output. For light resistive loads ( $>10 \mathrm{k} \Omega$ ), the output voltage swing is typically a ten millivolts from the supply rails. With heavier resistive loads ( $600 \Omega$ to $10 \mathrm{k} \Omega$ ), the output can swing to within a few tens of millivolts from the supply rails and maintain high openloop gain. See the typical performance curves "Output Voltage Swing vs Output Current" and "Open-Loop Gain vs Output Voltage."

## CAPACITIVE LOAD AND STABILITY

OPA350 series op amps can drive a wide range of capacitive loads. However, all op amps under certain conditions may become unstable. Op amp configuration, gain, and load value are just a few of the factors to consider when determining stability. An op amp in unity gain configuration is the most susceptible to the effects of capacitive load. The capacitive load reacts with the op amp's output impedance, along with any additional load resistance, to create a pole in the small-signal response which degrades the phase margin.
In unity gain, OPA350 series op amps perform well with very large capacitive loads. Increasing gain enhances the amplifier's ability to drive more capacitance. The typical
performance curve "Small-Signal Overshoot vs Capacitive Load" shows performance with a $1 \mathrm{k} \Omega$ resistive load. Increasing load resistance improves capacitive load drive capability.

## FEEDBACK CAPACITOR IMPROVES RESPONSE

For optimum settling time and stability with high-impedance feedback networks, it may be necessary to add a feedback capacitor across the feedback resistor, $\mathrm{R}_{\mathrm{F}}$, as shown in Figure 4. This capacitor compensates for the zero created by the feedback network impedance and the OPA350's input capacitance (and any parasitic layout capacitance). The effect becomes more significant with higher impedance networks.

Where $\mathrm{C}_{\mathrm{I}_{\mathrm{N}}}$ is equal to the OPA350's input capacitance (approximately 9 pF ) plus any parastic layout capacitance.

FIGURE 4. Feedback Capacitor Improves Dynamic Performance.

It is suggested that a variable capacitor be used for the feedback capacitor since input capacitance may vary between op amps and layout capacitance is difficult to determine. For the circuit shown in Figure 4, the value of the variable feedback capacitor should be chosen so that the input resistance times the input capacitance of the OPA350 (typically 9pF) plus the estimated parasitic layout capacitance equals the feedback capacitor times the feedback resistor:

$$
\mathrm{R}_{\mathrm{IN}} \cdot \mathrm{C}_{\mathrm{IN}}=\mathrm{R}_{\mathrm{F}} \cdot \mathrm{C}_{\mathrm{F}}
$$

where $\mathrm{C}_{\text {IN }}$ is equal to the OPA350's input capacitance (sum of differential and common-mode) plus the layout capacitance. The capacitor can be varied until optimum performance is obtained.

## DRIVING A/D CONVERTERS

OPA350 series op amps are optimized for driving medium speed (up to 500 kHz ) sampling A/D converters. However, they also offer excellent performance for higher speed converters. The OPA350 series provides an effective means of buffering the A/D's input capacitance and resulting charge injection while providing signal gain.

Figure 5 shows the OPA350 driving an ADS7861. The ADS7861 is a dual, 500 kHz 12 -bit sampling converter in the tiny SSOP-24 package. When used with the miniature package options of the OPA350 series, the combination is ideal for space-limited applications. For further information, consult the ADS7861 data sheet.

## OUTPUT IMPEDANCE

The low frequency open-loop output impedance of the OPA350's common-source output stage is approximately $1 \mathrm{k} \Omega$. When the op amp is connected with feedback, this value is reduced significantly by the loop gain of the op amp. For example, with 122 dB of open-loop gain, the output impedance is reduced in unity-gain to less than $0.001 \Omega$. For each decade rise in the closed-loop gain, the loop gain is reduced by the same amount which results in a ten-fold increase in effective output impedance (see the typical performance curve, "Output Impedance vs Frequency").
At higher frequencies, the output impedance will rise as the open-loop gain of the op amp drops. However, at these frequencies the output also becomes capacitive due to parasitic capacitance. This prevents the output impedance
from becoming too high, which can cause stability problems when driving capacitive loads. As mentioned previously, the OPA350 has excellent capacitive load drive capability for an op amp with its bandwidth.

## VIDEO LINE DRIVER

Figure 6 shows a circuit for a single supply, $\mathrm{G}=2$ composite video line driver. The synchronized outputs of a composite video line driver extend below ground. As shown, the input to the op amp should be ac-coupled and shifted positively to provide adequate signal swing to account for these negative signals in a single-supply configuration.
The input is terminated with a $75 \Omega$ resistor and ac-coupled with a $47 \mu \mathrm{~F}$ capacitor to a voltage divider that provides the dc bias point to the input. In Figure 6, this point is approximately (V-) +1.7 V . Setting the optimal bias point requires some understanding of the nature of composite video signals. For best performance, one should be careful to avoid the distortion caused by the transition region of the OPA350's complementary input stage. Refer to the discussion of rail-to-rail input.

## IMPORTANT NOTICE

Texas Instruments and its subsidiaries (TI) reserve the right to make changes to their products or to discontinue any product or service without notice, and advise customers to obtain the latest version of relevant information to verify, before placing orders, that information being relied on is current and complete. All products are sold subject to the terms and conditions of sale supplied at the time of order acknowledgment, including those pertaining to warranty, patent infringement, and limitation of liability.

TI warrants performance of its semiconductor products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

Customers are responsible for their applications using TI components.
In order to minimize risks associated with the customer's applications, adequate design and operating safeguards must be provided by the customer to minimize inherent or procedural hazards.

TI assumes no liability for applications assistance or customer product design. TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used. Tl's publication of information regarding any third party's products or services does not constitute Tl's approval, warranty or endorsement thereof.
