

## Bi-CMOS 8-BIT SERIAL-INPUT LATCHED DRIVER

**DESCRIPTION**

The M54975 is a semiconductor integrated circuit fabricated using Bi-CMOS technology. It contains a serial input to serial/parallel output 8-bit CMOS shift register and CMOS latch as well as bipolar 8-bit parallel-output driver.

**FEATURES**

- Serial input to serial/parallel output
- Cascade connections possible through serial output
- Latch circuit included for each stage
- Enable input for output control
- Low supply current .....  $I_{CC} \geq 10\mu A$  at standby
- Serial input/output level is compatible with standard CMOS
- Driver : Withstand voltage .....  $BV_{CEO} \geq 30V$   
Large drive current ..... ( $I_O(max)=300mA$ )
- Wide operating temperature range .....  $T_a=-20 - +75^{\circ}C$

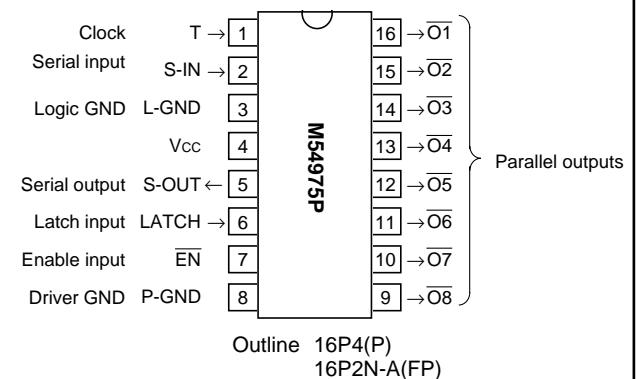

**APPLICATION**

Thermal printer head dot driver, Serial-to parallel conversion, Relay and Solenoid driver

**FUNCTION**

The M54975 consists of an 8-bit D-type flip-flop, the output of which is connected to 8 latches.

When data is applied to the serial data input (S-IN) and a clock pulse is applied to clock input (T), an "L" to "H" change of the clock will cause the data input signals to enter the internal shift registers and the data in the shift registers will be shifted in order.

**PIN CONFIGURATION (TOP VIEW)**

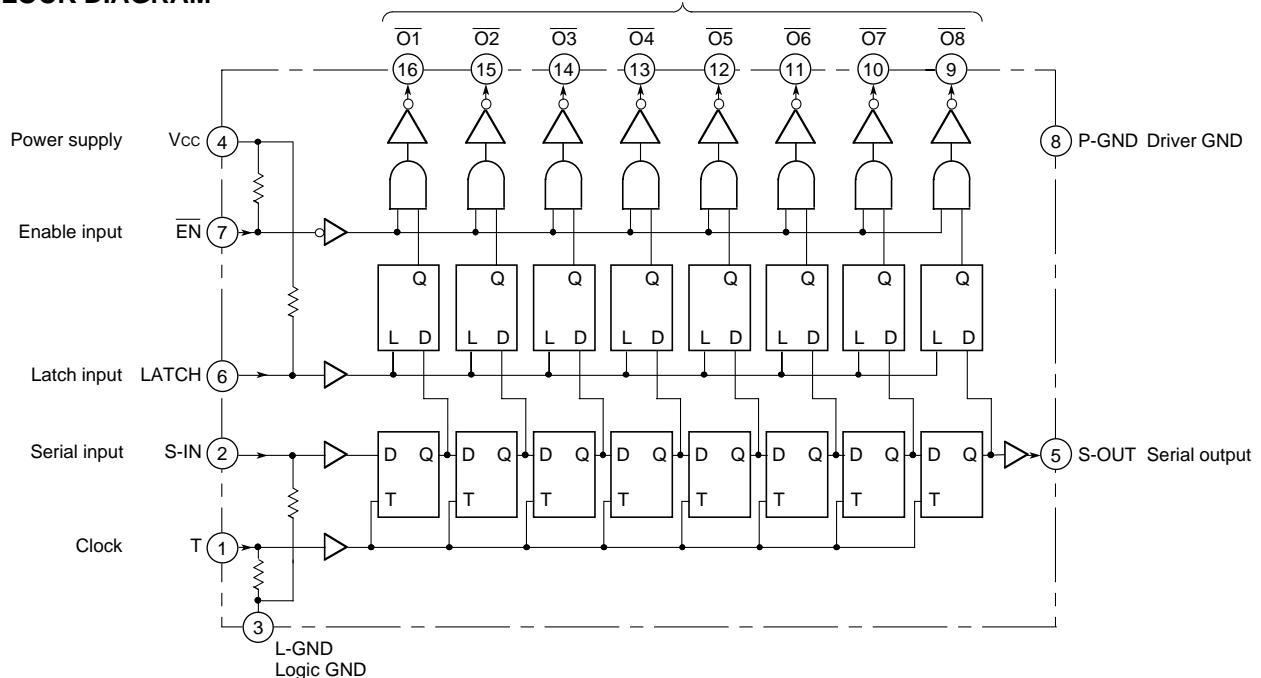

Using a number of M54975 units for bit expansion in series will entail connecting serial output (S-OUT) to S-IN of the next-stage M54975.

In parallel output, when the latch input is set to "H" and the output-control input (enable input  $\overline{EN}$ ) is "L", a clock pulse changing from "L" to "H" will cause the serial data input signal to appear at output  $\overline{O}_1$ , and the data will be shifted in order at outputs  $\overline{O}_2 - \overline{O}_8$ .

The parallel output will yield a signal that is inverted with respect to the serial data input.

Setting the LATCH input to "L" will prevent data from entering the latch.

When the  $\overline{EN}$  input is set to "H", all outputs ( $\overline{O}_1 - \overline{O}_8$ ) will be set to OFF. Since the internal logic state of the IC is uncertain at power-on time, set the  $\overline{EN}$  input to "H" (and outputs  $\overline{O}_1 - \overline{O}_8$  will set to

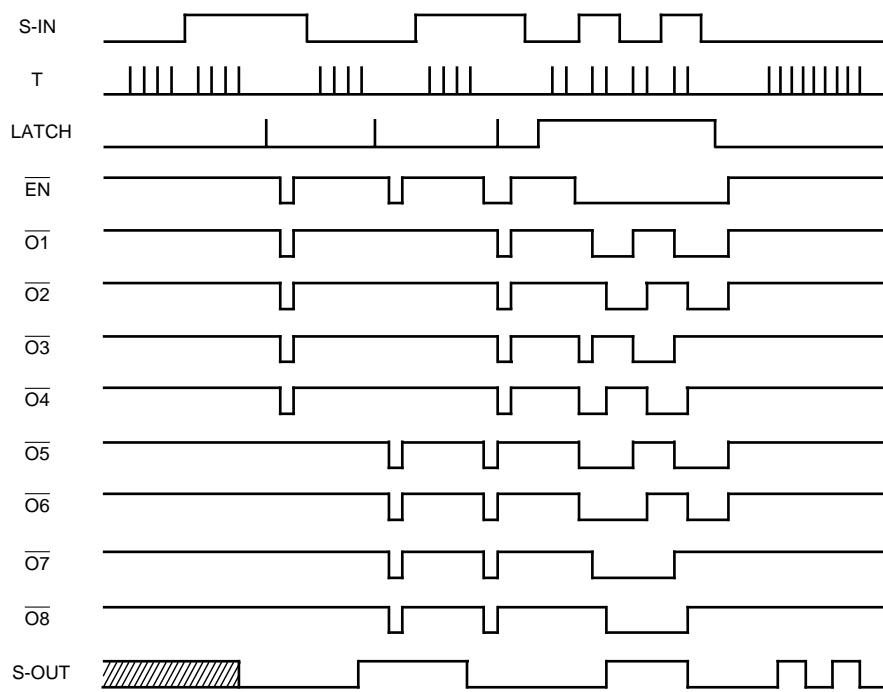

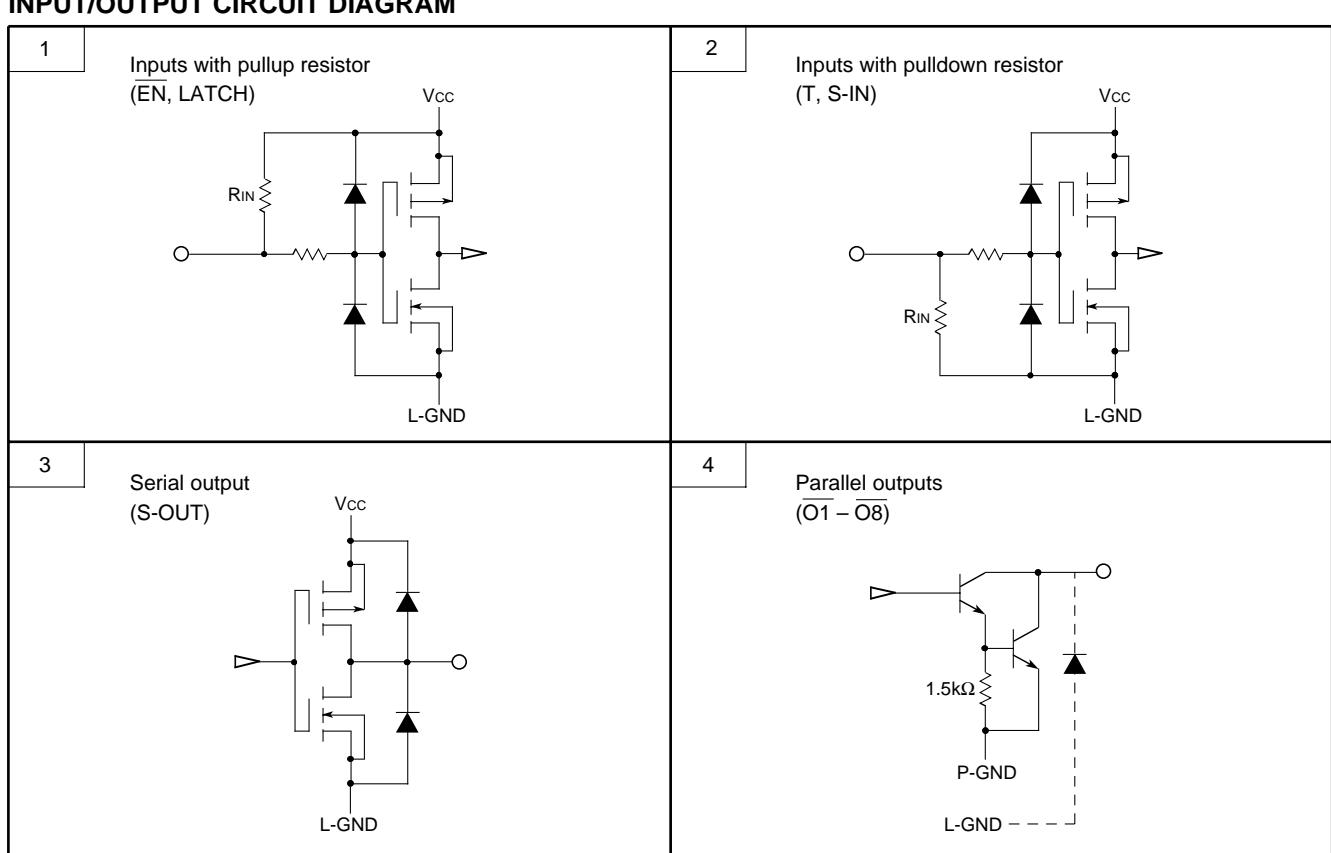

**BLOCK DIAGRAM**

OFF) until the input data is set and the internal logic state has been determined.

L-GND is the ground of the CMOS logic circuit section and P-GND

is the ground for the output driver section ( $\overline{O_1}$  –  $\overline{O_8}$ ), which is made up of bipolar transistors that are capable of driving large currents.
