## PIN DESCRIPTIONS

Pin Names	Type	Description
AGND	Gnd	Analog ground.
A(TIP)	Output	Output of A(TIP) power amplifier.
BGND	Gnd	Battery (power) ground.
B(RING)	Output	Output of B(RING) power amplifier.
C3–C1	Inputs	Decoder. TTL compatible. C3 is MSB and C1 is LSB.
C4	Input	Test relay driver command. TTL compatible. A logic High enables the driver.
DGND	Gnd	Digital ground.
CHCLK	Input	Chopper clock. Input to switching regulator (TTL compatible) Frequency = 256 kHz (nominal).
CHS	Input	Chopper stabilization. Connection for external stabilization components.
DA	Input	Ring-Trip negative. Negative input to ring-trip comparator.
DB	Input	Ring-Trip positive. Positive input to ring-trip comparator.
DET	Output	Detector. When enabled, a logic Low indicates that the selected detector is tripped. The detector is selected by the logic inputs (C3–C1 and E1). The output is open-collector with a built-in 15 k $\Omega$ pull-up resistor.
E0	Input	Read enable. A logic High enables $\overline{\text{DET}}$ . A logic Low disables $\overline{\text{DET}}$ .
E1	Input	Ground key enable. E1 = High connects the ground-key detector to $\overline{\text{DET}}$ , and E1 = Low connects the off-hook or ring-trip detector to $\overline{\text{DET}}$ .
HPA	Capacitor	High-pass filter capacitor. A(TIP) side of high-pass filter capacitor.
HPB	Capacitor	High-pass filter capacitor. B(RING) side of high-pass filter capacitor.
L	Output	Switching regulator power transistor. Connection point for filter inductor and anode of catch diode. This pin will have up to 60 V of pulse waveform on it and must be isolated from sensitive circuits. Extreme care must be taken to keep the diode connections short because of the high currents and high di/dt.
QBAT	Battery	Quiet battery. Filtered battery supply for the signal processing circuits. An external 100 $\Omega$ , 1/8 $\Omega$ resistor must be connected between QBAT and VBAT pins.
RD	Resistor	Detect resistor. Threshold modification and filter point for the off-hook detector.
RDC	Resistor	DC feed resistor. Connection point for the DC feed current programming network. The other end of the network connects to the receiver summing node (RSN). The sign of $V_{\text{RDC}}$ is negative for normal polarity and positive for reverse polarity.
RINGOUT	Output	Ring relay driver. Sourcing from BGND with internal diode to QBAT.
RSN	Input	Receive summing node. The metallic current (both AC and DC) between A(TIP) and B(RING) is equal to 1000 times the current into this pin. The networks that program receive gain, two-wire impedance, and feed current all connect to this node. This node is extremely sensitive. Care should be taken to route the 256-kHz chopper clock and switch lines away from the RSN node.
TESTOUT	Output	Test relay driver. Sourcing from BGND with internal diode to QBAT.
TP	Thermal	Thermal pin. Connection for heat dissipation. Internally connected to substrate (QBAT). Leave as open circuit or connected to QBAT. In both cases, the TP pins can connect to an area of copper on the board to enhance heat dissipation.
VBAT	Battery	Battery Supply.
VCC	Power	+5 V power supply.
VEE	Power	–5 V power supply.
VREG	Input	Regulated voltage. Provides negative power supply for power amplifiers, connection point for inductor, filter capacitor, and chopper stabilization.
VTX	Output	Transmit audio. This output is a unity gain version of the A(TIP) and B(RING) metallic voltage. The other end of the two-wire input impedance programming network connects here.

## SWITCHING WAVEFORMS

E1 to  $\overline{\text{DET}}$

E0 to  $\overline{\text{DET}}$

**Note:**

All delays measured at 1.4 V level.

**Notes:**

1. Unless otherwise noted, test conditions are  $BAT = -60\text{ V}$ ,  $V_{CC} = +5\text{ V}$ ,  $V_{EE} = -5\text{ V}$ ,  $R_L = 600\ \Omega$ ,  $C_{HP} = 0.33\ \mu\text{F}$ ,  $R_{DC1} = R_{DC2} = 31.25\ \text{k}\Omega$ ,  $C_{DC} = 0.1\ \mu\text{F}$ ,  $R_d = 51.1\ \text{k}\Omega$ , no fuse resistors, two-wire AC output impedance programming impedance ( $Z_T$ ) =  $600\ \text{k}\Omega$  resistive, receive input summing impedance ( $Z_{RX}$ ) =  $300\ \text{k}\Omega$  resistive. (See Table 2 for component formulas.)
2. Overload level is defined when  $THD = 1\%$ .
3. Balance return signal is the signal generated at  $V_{TX}$  by  $V_{RX}$ . This specification assumes that the two-wire AC load impedance matches the impedance programmed by  $Z_T$ .
4. Not tested in production. This parameter is guaranteed by characterization or correlation to other tests.
5. These tests are performed with a longitudinal impedance of  $90\ \Omega$  and metallic impedance of  $300\ \Omega$  for frequencies below  $12\ \text{kHz}$  and  $135\ \Omega$  for frequencies greater than  $12\ \text{kHz}$ . These tests are extremely sensitive to circuit board layout. Please refer to application notes for details.
6. This parameter is tested at  $1\ \text{kHz}$  in production. Performance at other frequencies is guaranteed by characterization.
7. When the SLIC is in the Anti-Sat 2 operating region, this parameter is degraded. The exact degradation depends on system design. The Anti-Sat 2 region occurs at high loop resistances when  $|V_{BAT}| - |V_{AX} - V_{BX}|$  is less than approximately  $15\ \text{V}$ .
8. "Midpoint" is defined as the connection point between two  $300\ \Omega$  series resistors connected between A(TIP) and B(RING).
9. Fundamental and harmonics from  $256\ \text{kHz}$  switch regulator chopper are not included.

**Table 2. User-Programmable Components**

$Z_T = 1000(Z_{2WIN} - 2R_F)$	Where $Z_T$ is connected between the VTX and RSN pins. The fuse resistors are $R_F$ , and $Z_{2WIN}$ is the desired 2-wire AC input impedance. When computing $Z_T$ , the internal current amplifier pole and any external stray capacitance between VTX and RSN must be taken into account.
$Z_{RX} = \frac{Z_L}{G_{42L}} \cdot \frac{1000 \cdot Z_T}{Z_T + 1000(Z_L + 2R_F)}$	Where $Z_{RX}$ is connected from $V_{RX}$ to the RSN pin, $Z_T$ is defined above, $G_{42L}$ is the desired receive gain, and $Z_L$ is the 2-wire load impedance.
$R_{DC1} + R_{DC2} = \frac{2500}{I_{FEED}}$	Where $R_{DC1}$ , $R_{DC2}$ , and $C_{DC}$ form the network $C_{DC} = (1.5 \text{ ms})(R_{DC1} + R_{DC2})/(R_{DC1} \cdot R_{DC2})$ connected to the RDC pin. $R_{DC1}$ and $R_{DC2}$ are approximately equal.
$R_D = \frac{365}{I_T}, \quad C_D = \frac{0.5 \text{ ms}}{R_D}$	Where $R_D$ and $C_D$ form the network connected from RD to $-5 \text{ V}$ and $I_T$ is the threshold current between on hook and off hook.
