

July 2005

Features

- 4096 channel x 4096 channel non-blocking digital Time Division Multiplex (TDM) switch at 8.192 Mbps and 16.384 Mbps or using a combination of ports running at 2.048, 4.096, 8.192 and 16.384 Mbps
- 32 serial TDM input, 32 serial TDM output streams
- Integrated Digital Phase-Locked Loop (DPLL) exceeds Telcordia GR-1244-CORE Stratum 4E specifications
- Output clocks have less than 1 ns of jitter (except for the 1.544 MHz output)
- DPLL provides holdover, freerun and jitter attenuation features with four independent reference source inputs

Ordering Information

ZL50022GAC	256 Ball PBGA	Trays
ZL50022QCC	256 Lead LQFP	Trays

-40°C to +85°C

- Exceptional input clock cycle to cycle variation tolerance (20 ns for all rates)
- Output streams can be configured as bi-directional for connection to backplanes
- Per-stream input and output data rate conversion selection at 2.048 Mbps, 4.096 Mbps, 8.192 Mbps or 16.384 Mbps. Input and output data rates can differ

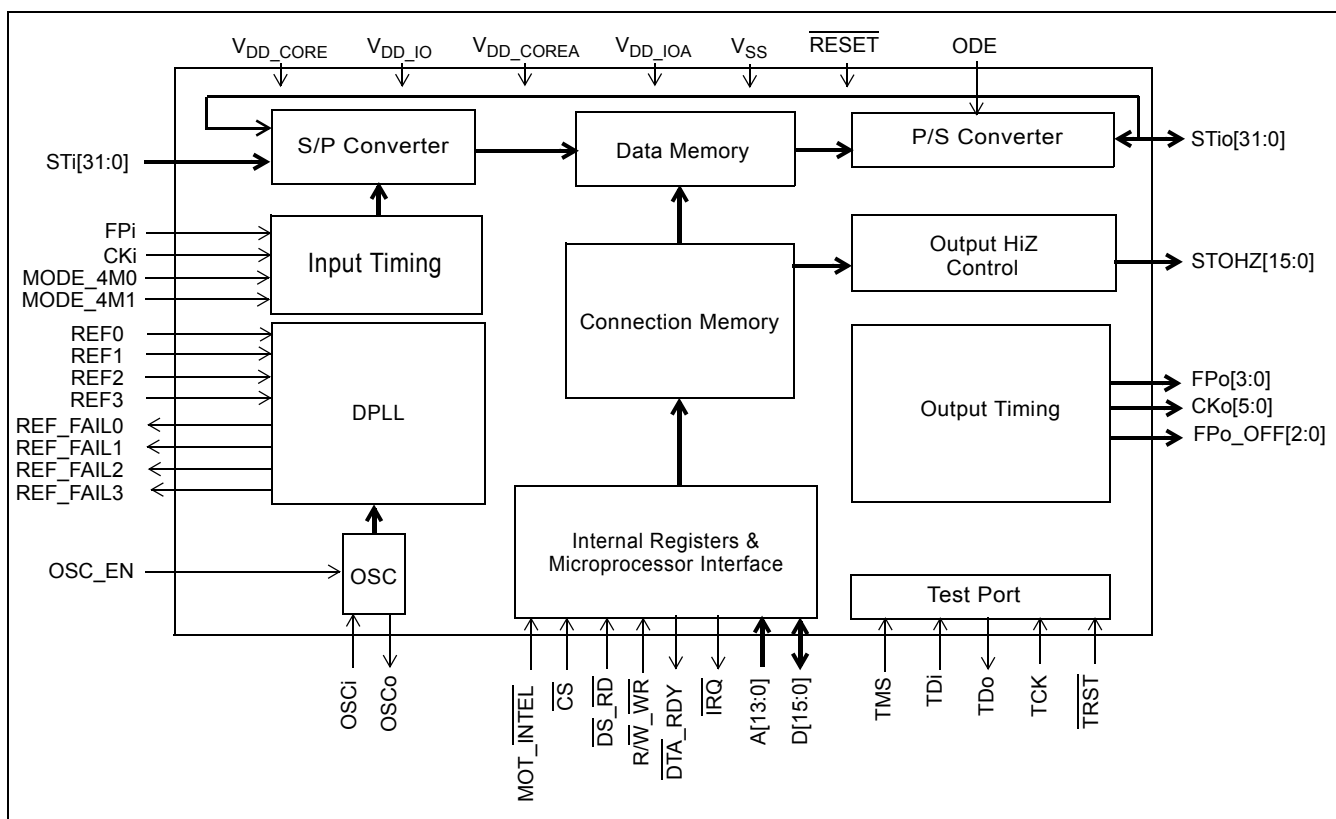

Figure 1 - ZL50022 Functional Block Diagram

**Zarlink Semiconductor US Patent No. 5,602,884, UK Patent No. 0772912,
 France Brevete S.G.D.G. 0772912; Germany DBP No. 69502724.7-08**

- Per-stream high impedance control outputs (STOHZ) for 16 output streams
- Per-stream input bit delay with flexible sampling point selection
- Per-stream output bit and fractional bit advancement
- Per-channel ITU-T G.711 PCM A-Law/ μ -Law Translation
- Four frame pulse and six reference clock outputs
- Three programmable delayed frame pulse outputs
- Input clock: 4.096 MHz, 8.192 MHz, 16.384 MHz
- Input frame pulses: 61 ns, 122 ns, 244 ns
- Per-channel constant or variable throughput delay for frame integrity and low latency applications
- Per Stream (32) Bit Error Rate Test circuits complying to ITU-O.151
- Per-channel high impedance output control
- Per-channel message mode
- Control interface compatible with Intel and Motorola 16-bit non-multiplexed buses
- Connection memory block programming
- Supports ST-BUS and GCI-Bus standards for input and output timing
- IEEE-1149.1 (JTAG) test port
- 3.3 V I/O with 5 V tolerant inputs; 1.8 V core voltage

Applications

- PBX and IP-PBX
- Small and medium digital switching platforms
- Remote access servers and concentrators
- Wireless base stations and controllers
- Multi service access platforms
- Digital Loop Carriers
- Computer Telephony Integration

Description

The ZL50022 is a maximum 4,096 x 4,096 channel non-blocking digital Time Division Multiplex (TDM) switch. It has thirty-two input streams (STi0 - 31) and thirty-two output streams (STio0 - 31). The device can switch 64 kbps and Nx64 kbps TDM channels from any input stream to any output stream. Each of the input and output streams can be independently programmed to operate at any of the following data rates: 2.048 Mbps, 4.096 Mbps, 8.192 Mbps or 16.384 Mbps. The ZL50022 provides up to sixteen high impedance control outputs (STOHZ0 - 15) to support the use of external tristate drivers for the first sixteen output streams (STio0 - 15). The output streams can be configured to operate in bi-directional mode, in which case STi0 - 31 will be ignored.

The device contains two types of internal memory - data memory and connection memory. There are four modes of operation - Connection Mode, Message Mode, BER mode and high impedance mode. In Connection Mode, the contents of the connection memory define, for each output stream and channel, the source stream and channel (the actual data to be output is stored in the data memory). In Message Mode, the connection memory is used for the storage of microprocessor data. Using Zarlink's Message Mode capability, microprocessor data can be broadcast to the data output streams on a per-channel basis. This feature is useful for transferring control and status information for external circuits or other TDM devices. In BER mode the output channel data is replaced with a pseudo-random bit sequence (PRBS) from one of 32 PRBS generators that generates a $2^{15}-1$ pattern. On the input side channels can be routed to one of 32-bit error detectors. In high impedance mode the selected output channel can be put into a high impedance state.

When the device is operating as a timing master, the internal digital PLL is in use. In this mode, an external 20.000 MHz crystal is required for the on-chip crystal oscillator. The DPLL is phase-locked to one of four input reference signals (which can be 8 kHz, 1.544 MHz, 2.048 MHz, 4.096 MHz, 8.192 MHz, 16.384 MHz or 19.44 MHz provided on REF0 - 3). The on-chip DPLL operates in normal, holdover or freerun mode and offers jitter attenuation. The jitter attenuation function exceeds the Stratum 4E specification.

The configurable non-multiplexed microprocessor port allows users to program various device operating modes and switching configurations. Users can employ the microprocessor port to perform register read/write, connection memory read/write, and data memory read operations. The port is configurable to interface with either Motorola or Intel-type microprocessors.

The device also supports the mandatory requirements of the IEEE-1149.1 (JTAG) standard via the test port.

Changes Summary

The following table captures the changes from the October 2004 issue.

Page	Item	Change
39, 70, 71	Section 12.1, "DPLL Timing Modes" on page 39 RCCR Register bits "FDM1 - 0" on page 70 RCSR Register bits "DPM1 - 0" on page 71	<ul style="list-style-type: none">The on-chip DPLL's normal, holdover, automatic, and freerun modes are now collectively referred to as DPLL timing modes instead of operation modes. This change is to avoid confusion with the two main device operating modes; the master and slave modes.
40	Section 12.1.3.1, "Automatic Reference Switching Without Preferences" on page 40 and Section 12.1.3.2, "Automatic Reference Switching With Preferences" on page 41	<ul style="list-style-type: none">Section 12.1.3.1 and Section 12.1.3.2 added to clarify the DPLL's automatic reference switching with and without preference operations in Automatic Timing Mode.
67	Table 33, Lock Detector Threshold Register (LDTR) Bits	<ul style="list-style-type: none">Clarified threshold calculations.
69	Table 36, "Reference Change Control Register (RCCR) Bits" Bits "PRS1 - 0" and Bits "PMS2 - 0"	<ul style="list-style-type: none">Added description to clarify that only two consecutive references can be used in automatic timing mode with a preferred reference.

PBGA Pin Number	LQFP Pin Number	Pin Name	Description
K3	234	TMS	Test Mode Select (5 V-Tolerant Input with Internal Pull-up) JTAG signal that controls the state transitions of the TAP controller. This pin is pulled high by an internal pull-up resistor when it is not driven.
L4	238	TCK	Test Clock (5 V-Tolerant Schmitt-Triggered Input with Internal Pull-up) Provides the clock to the JTAG test logic.
L3	239	$\overline{\text{TRST}}$	Test Reset (5 V-Tolerant Input with Internal Pull-up) Asynchronously initializes the JTAG TAP controller by putting it in the Test-Logic-Reset state. This pin should be pulsed low during power-up to ensure that the device is in the normal functional mode. When JTAG is not being used, this pin should be pulled low during normal operation.
M3	240	TDi	Test Serial Data In (5 V-Tolerant Input with Internal Pull-up) JTAG serial test instructions and data are shifted in on this pin. This pin is pulled high by an internal pull-up resistor when it is not driven.
G5	212	TDo	Test Serial Data Out (5 V-Tolerant Three-state Output) JTAG serial data is output on this pin on the falling edge of TCK. This pin is held in high impedance state when JTAG is not enabled.
B12, B13, C10, C11, F13, G4, K12	80, 105, 150, 151, 152, 153, 210	IC_OPEN	Internal Test Mode (5 V-Tolerant Input with Internal Pull-down) These pins may be left unconnected.
C13, G3	144, 208	IC_GND	Internal Test Mode Enable (5 V-Tolerant Input) These pins MUST be low.
A8, A9, A14, A15, E10, M2, N2, P2, P16, R2, R16, T6, T7, T8, T9, T10, T11, T12, T13, T14, T15	61, 62, 63, 64, 65, 66, 67, 68, 134, 135, 136, 137, 138, 139, 140, 215, 219, 225, 229, 236, 237	NC	No Connect These pins MUST be left unconnected.

PBGA Pin Number	LQFP Pin Number	Pin Name	Description
M14, R13	46, 48	MODE_4M0, MODE_4M1	4M Input Clock Mode 0 to 1 (5V-Tolerant Input with internal pull-down) These two pins should be tied together and are typically used to select CKi = 4.096MHz operation. See Table 7, “ZL50022 Operating Modes” on page 38 for a detailed explanation. See Table 17, “Control Register (CR) Bits” on page 53 for CKi and FPi selection using the CKIN1 - 0 bits.
D12	107	OSC_EN	Oscillator Enable (5 V-Tolerant Input with Internal Pull-down) If tied high, this pin indicates that there is a 20 MHz external oscillator interfacing with the device. If tied low, there is no oscillator and CKi will be used for master clock generation. If the device is in master mode, an external oscillator is required and this pin MUST be tied high.
C12	149	OSCo	Oscillator Clock Output (3.3 V Output) If OSC_EN = ‘1’, this pin should be connected to a 20 MHz crystal (See Figure 23 on page 90) or left unconnected if a clock oscillator is connected to OSCi pin under normal operation (See Figure 24 on page 91). If OSC_EN = 0, this pin MUST be left unconnected.
B14	148	OSCi	Oscillator Clock Input (3.3 V Input) If OSC_EN = ‘1’, this pin should be connected to a 20 MHz crystal (See Figure 23 on page 90) or to a clock oscillator under normal operation (See Figure 24 on page 91). If OSC_EN = 0, this pin MUST be driven high or low by connecting either to V _{DD_IO} or to ground.
E9, D8, B8, D7	161, 164, 166, 168	REF0 - 3	DPLL Reference Inputs 0 to 3 (5 V-Tolerant Schmitt-Triggered Inputs) If the device is in Master mode, these input pins accept 8 kHz, 1.544 MHz, 2.048 MHz, 4.096 MHz, 8.192 MHz, 16.384 MHz or 19.44 MHz timing references independently. One of these inputs is defined as the preferred or forced input reference for the DPLL. The Reference Change Control Register (RCCR) selects the control of the preferred reference. These pins are ignored if the device is in slave mode unless SLV_DPLLEN (bit 13) in the Control Register (CR) is set. When these input pins are not in use, they MUST be driven high or low by connecting either to V _{DD_IO} or to ground.
D9, E8, C8, E7	159, 163, 165, 167	REF_FAIL0 - 3	Failure Indication for DPLL References 0 to 3 (5 V-Tolerant Three-state Outputs) These output pins are used to indicate input reference failure when the device is in master mode. If REF0 fails, REF_FAIL0 will be driven high. If REF1 fails, REF_FAIL1 will be driven high. If REF2 fails, REF_FAIL2 will be driven high. If REF3 fails, REF_FAIL3 will be driven high. If the device is in slave mode, these pins are driven low, unless SLV_DPLLEN (bit 13) in the Control Register (CR) is set.

PBGA Pin Number	LQFP Pin Number	Pin Name	Description
G15, G14, E15, F14	102, 106, 110, 112	FPo0 - 3	ST-BUS/GCI-Bus Frame Pulse Outputs 0 to 3 (5 V-Tolerant Three-state Outputs) FPo0: 8 kHz frame pulse corresponding to the 4.096 MHz output clock of CKo0. FPo1: 8 kHz frame pulse corresponding to the 8.192 MHz output clock of CKo1. FPo2: 8 kHz frame pulse corresponding to 16.384 MHz output clock of CKo2. FPo3: Programmable 8 kHz frame pulse corresponding to 4.096 MHz, 8.192 MHz, 16.384 MHz, or 32.768 MHz output clock of CKo3. In Divided Slave modes, the frame pulse width of FPo0 - 3 cannot be narrower than the input frame pulse (FPi) width.
H14, D11	100, 104	FPo_OFF0 - 1	Generated Offset Frame Pulse Outputs 0 to 1 (5 V-Tolerant Three-state Outputs) Individually programmable 8 kHz frame pulses, offset from the output frame boundary by a programmable number of channels.
F15	108	FPo_OFF2 or FPo5	Generated Offset Frame Pulse Output 2 or 19.44 MHz Frame Pulse Output (5 V-Tolerant Three-state Output) As FPo_OFF2, this is an individually programmable 8 kHz frame pulse, offset from the output frame boundary by a programmable number of channels. By programming the FP19EN (bit 10) of FPOFF2 register to high, this signal becomes FPo5, a non-offset frame pulse corresponding to the 19.44 MHz clock presented on CKo5. FPo5 is only available in Master mode or when the SLV_DPLEN bit in the Control Register is set high while the device is in one of the slave modes.
B7, C7, B5, J6, D6, H5	170, 172, 174, 227, 176, 221	CKo0 - 5	ST-BUS/GCI-Bus Clock Outputs 0 to 5 (5 V-Tolerant Three-state Outputs) CKo0: 4.096 MHz output clock. CKo1: 8.192 MHz output clock. CKo2: 16.384 MHz output clock. CKo3: 4.096 MHz, 8.192 MHz, 16.384 MHz or 32.768 MHz programmable output clock. CKo4: 1.544 MHz or 2.048 MHz programmable output clock. CKo5: 19.44 MHz output clock See Section 6.0 on page 24 for details. In Divided Slave mode, the frequency of CKo0 - 3 cannot be higher than input clock (CKi). CKo4 and CKo5 are only available in Master mode or when the SLV_DPLEN bit in the Control Register is set high while the device is in one of the slave modes.

PBGA Pin Number	LQFP Pin Number	Pin Name	Description
B10	155	FPI	<p>ST-BUS/GCI-Bus Frame Pulse Input (5 V-Tolerant Schmitt-Triggered Input)</p> <p>This pin accepts the frame pulse which stays active for 61 ns, 122 ns or 244 ns at the frame boundary. The frame pulse frequency is 8 kHz. The frame pulse associated with the highest input or output data rate must be applied to this pin when the device is operating in Divided Slave mode or Master mode. The exception is if the device is operating in Master mode with loopback (i.e., CKI_LP is set in the Control Register). In that case, this input must be tied high or low externally. When the device is operating in Multiplied Slave mode, the frame pulse associated with the highest input data rate must be applied to this pin. For all modes (except Master mode with loopback), if the data rate is 16.384 Mbps, a 61 ns wide frame pulse must be used. By default, the device accepts a negative frame pulse in ST-BUS format, but it can accept a positive frame pulse instead if the FPINP bit is set high in the Control Register (CR). It can accept a GCI-formatted frame pulse by programming the FPINPOS bit in the Control Register (CR) to high.</p>
B11	154	CKi	<p>ST-BUS/GCI-Bus Clock Input (5 V-Tolerant Schmitt Triggered The Input)</p> <p>This pin accepts a 4.096 MHz, 8.192 MHz or 16.384 MHz clock. The clock frequency associated with twice the highest input or output data rate must be applied to this pin when the device is operating in either Divided Slave mode or Master mode. The exception is if the device is operating in Master mode with loopback (i.e., CKI_LP is set in the Control Register). In that case, this input must be tied high or low externally. The clock frequency associated with twice the highest input data rate must be applied to this pin when the device is operating in Multiplied Slave mode. In all modes of operation (except Master mode with loopback), when data is running at 16.384 Mbps, a 16.384 MHz clock must be used. By default, the clock falling edge defines the input frame boundary, but the device allows the clock rising edge to define the frame boundary by programming the CKINP bit in the Control Register (CR).</p>

In the 2.048 Mbps mode, these pins output serial TDM data streams at 2.048 Mbps with 32 channels per frame. In the 4.096 Mbps mode, these pins output serial TDM data streams at 4.096 Mbps with 64 channels per frame. In the 8.192 Mbps mode, these pins output serial TDM data streams at 8.192 Mbps with 128 channels per frame. In the 16.384 Mbps mode, these pins output serial TDM data streams at 16.384 Mbps with 256 channels per frame. These output streams can be used as bi-directionals by programming BDH (bit 7) and BDL (bit 6) of Internal Mode Selection (IMS) register.
R3, P6, R5, N5, P12, N15, P13, P15, N16, M16, L16, K16, H16, J16, G16, F16	11, 12, 13, 14, 55, 56, 58, 59, 75, 76, 77, 78, 119, 120, 122, 124	STOHZ0 - 15	Serial Output Streams High Impedance Control 0 to 15 (5 V-Tolerant Slew-Rate-Limited Three-state Outputs) These pins are used to enable (or disable) external three-state buffers. When an output channel is in the high impedance state, the STOHZ drives high for the duration of the corresponding output channel. When the STio channel is active, the STOHZ drives low for the duration of the corresponding output channel. STOHZ outputs are available for STio0 - 15 only.

PBGA Pin Number	LQFP Pin Number	Pin Name	Description
B15	141	ODE	Output Drive Enable (5 V-Tolerant Input with Internal Pull-up) This is the output enable control for STio0 - 31 and the output-driven-high control for STOHZ0 - 15. When it is high, STio0 - 31 and STOHZ0 - 15 are enabled. When it is low, STio0 - 31 are tristated and STOHZ0 - 15 are driven high.
M4, N6, R6, P7, R7, N7, M8, N8, P8, R8, M9, N9, R9, N10, P9, R10	16, 18, 20, 22, 23, 24, 25, 26, 27, 28, 30, 32, 34, 36, 37, 38	D0 - 15	Data Bus 0 to 15 (5 V-Tolerant Slew-Rate-Limited Three-state I/Os) These pins form the 16-bit data bus of the microprocessor port.
N12	44	$\overline{\text{DTA_RDY}}$	Data Transfer Acknowledgment_Ready (5 V-Tolerant Three-state Output) This active low output indicates that a data bus transfer is complete for the Motorola interface. For the Intel interface, it indicates a transfer is completed when this pin goes from low to high. An external pull-up resistor MUST hold this pin at HIGH level for the Motorola mode. An external pull-down resistor MUST hold this pin at LOW level for the Intel mode.
R11	40	$\overline{\text{CS}}$	Chip Select (5 V-Tolerant Input) Active low input used by the Motorola or Intel microprocessor to enable the microprocessor port access.
N11	39	$\text{R}/\overline{\text{W}}_{\overline{\text{WR}}}$	Read/Write_Write (5 V-Tolerant Input) This input controls the direction of the data bus lines (D0 - 15) during a microprocessor access. For the Motorola interface, this pin is set high and low for the read and write access respectively. For the Intel interface, a write access is indicated when this pin goes low.
R12	42	$\overline{\text{DS_RD}}$	Data Strobe_Read (5 V-Tolerant Input) This active low input works in conjunction with $\overline{\text{CS}}$ to enable the microprocessor port read and write operations for the Motorola interface. A read access is indicated when it goes low for the Intel interface.
K13, K15, K14, J11, J12, J13, J15, H11, J14, H12, H13, H15, G12, G13	82, 84, 86, 87, 88, 89, 90, 91, 92, 93, 94, 96, 98, 99	A0 - 13	Address 0 to 13 (5 V-Tolerant Inputs) These pins form the 14-bit address bus to the internal memories and registers.

PBGA Pin Number	LQFP Pin Number	Pin Name	Description
M13	41	MOT_ $\overline{\text{INTEL}}$	Motorola_Intel (5 V-Tolerant Input with Enabled Internal Pull-up) This pin selects the Motorola or Intel microprocessor interface to be connected to the device. When this pin is unconnected or connected to high, Motorola interface is assumed. When this pin is connected to ground, Intel interface should be used.
P10	43	$\overline{\text{IRQ}}$	Interrupt (5 V-Tolerant Three-state Output) This programmable active low output indicates that the internal operating status of the DPLL has changed. An external pull-up resistor MUST hold this pin at HIGH level.
G2	211	$\overline{\text{RESET}}$	Device Reset (5 V-Tolerant Input with Internal Pull-up) This input (active LOW) puts the device in its reset state that disables the STi0 - 31 drivers and drives the STOHZ0 - 15 outputs to high. It also preloads registers with default values and clears all internal counters. To ensure proper reset action, the reset pin must be low for longer than 1 μ s. Upon releasing the reset signal to the device, the first microprocessor access cannot take place for at least 600 μ s due to the time required to stabilize the device and the crystal oscillator from the power-down state. Refer to Section Section 17.2 on page 47 for details.

3.0 Device Overview

The device has thirty-two ST-BUS/GCI-Bus inputs (STi0 - 31) and thirty-two ST-BUS/GCI-Bus outputs (STio0 - 31). STi0 - 31 can also be configured as bi-directional pins, in which case STi0 - 31 will be ignored. It is a non-blocking digital switch with 4096 64 kbps channels and is capable of performing rate conversion between ST-BUS/GCI-Bus inputs and ST-BUS/GCI-Bus outputs. The ST-BUS/GCI-Bus inputs accept serial input data streams with data rates of 2.048 Mbps, 4.096 Mbps, 8.192 Mbps and 16.384 Mbps on a per-stream basis. The ST-BUS/GCI-Bus outputs deliver serial data streams with data rates of 2.048 Mbps, 4.096 Mbps and, 8.192 Mbps and 16.384 Mbps on a per-stream basis. The device also provides sixteen high impedance control outputs (STOHZ0 - 15) to support the use of external ST-BUS/GCI-Bus tristate drivers for the first sixteen ST-BUS/GCI-Bus outputs (STio0 -15).

By using Zarlink's message mode capability, microprocessor data stored in the connection memory can be broadcast to the output streams on a per-channel basis. This feature is useful for transferring control and status information for external circuits or other ST-BUS/GCI-Bus devices.

The device uses the ST-BUS/GCI-Bus input frame pulse (FPi) and the ST-BUS/GCI-Bus input clock (CKi) to define the input frame boundary and timing for sampling the ST-BUS/GCI-Bus input streams with various data rates. The output data streams will be driven by and have their timing defined by FPi and CKi in Divided Slave mode. In Multiplied Slave mode, the output data streams will be driven by an internally generated clock, which is multiplied from CKi internally. In Master mode, the on-chip DPLL will drive the output data streams and provide output clocks and frame pulses. Refer to Application Note ZLAN-120 for further explanation of the different modes of operation.

When the device is in Master mode, the DPLL is phase-locked to one of four DPLL reference signals, REF0 - 3, which are sourced by an external 8 kHz, 1.544 MHz, 2.048 MHz, 4.096 MHz, 8.192 MHz, 16.384 MHz or 19.44 MHz reference signal. The on-chip DPLL also offers jitter attenuation, reference switching, reference monitoring, freerun and holdover functions. The jitter performance exceeds the Stratum 4E specification. The intrinsic jitter of all output clocks is less than 1 ns (except for the 1.544 MHz output).

There are two slave modes for this device:

The first is the Divided Slave mode. In this mode, output streams are clocked by input CKi. Therefore the output streams have exactly the same jitter as the input streams. The output data rate can be the same as or lower than the input data rate, but the output data rate cannot be higher than what CKi can drive. For example, if CKi is 4.096 MHz, the output data rate cannot be higher than 2.048 Mbps. For the Divided Slave mode, the core master clock can be either 98.304 MHz, which is multiplied from CKi, or 100 MHz, which is multiplied from a 20 MHz oscillator. The Divided Slave mode with 98.304 MHz core master clock is called Divided Slave with CKi mode, and the mode with 100 MHz core master clock is called Divided Slave with OSC mode.

The second slave mode is called Multiplied Slave mode. In this mode, CKi is used to generate a 16.384 MHz clock internally, and output streams are driven by this 16.384 MHz clock. In Multiplied Slave mode, the data rate of output streams can be any rate, but output jitter may not be exactly the same as input jitter.

A Motorola or Intel compatible non-multiplexed microprocessor port allows users to program the device to operate in various modes under different switching configurations. Users can use the microprocessor port to perform internal register and memory read and write operations. The microprocessor port has a 16-bit data bus, a 14-bit address bus and six control signals (MOT_INTEL, CS, DS_RD, R/W_WR, IRQ and DTA_RDY).

The device supports the mandatory requirements of the IEEE-1149.1 (JTAG) standard via the test port.

4.0 Data Rates and Timing

The ZL50022 has 32 serial data inputs and 32 serial data outputs. Each stream can be individually programmed to operate at 2.048 Mbps, 4.096 Mbps, 8.192 Mbps or 16.384 Mbps. Depending on the data rate there will be 32 channels, 64 channels, 128 channels or 256 channels, respectively, during a 125 μ s frame.

The output streams can be programmed to operate as bi-directional streams. The output streams are divided into two groups to be programmed into bi-directional mode. By setting BDL (bit 6) in the Internal Mode Selection (IMS) register, input streams 0 - 15 (STi0 - 15) are internally tied low, and output streams 0 - 15 (STio0 - 15) are set to operate in a bi-directional mode. Similarly, when BDH (bit 7) in the Internal Mode Selection (IMS) register is set, input streams 16 - 31 (STi16 - 31) are internally tied low, and output streams 16 - 31 (STio16 - 31) are set to operate in bi-directional mode. The groups do not have to be set into the same mode. Therefore it is possible to have half of the streams operating in bi-directional mode while the other half is operating in normal input/output mode.

The input data rate is set on a per-stream basis by programming STIN[n]DR3 - 0 (bits 3 - 0) in the Stream Input Control Register 0 - 31 (SICR0 - 31). The output data rate is set on a per-stream basis by programming STO[n]DR3 - 0 (bits 3 - 0) in the Stream Output Control Register 0 - 31 (SOCR0 - 31). The output data rates do not have to match or follow the input data rates. The maximum number of channels switched is limited to 4096 channels. If all 32 input streams were operating at 16.384 Mbps (256 channels per stream), this would result in 8192 channels. Memory limitations prevent the device from operating at this capacity. A maximum capacity of 4096 channels will occur if half of the total streams are operating at 16.384 Mbps or all streams are operating at 8.192 Mbps. With all streams operating at 4.096 Mbps, the switching capacity is reduced to 2048 channels. And with all streams operating at 2.048 Mbps, the capacity will be further reduced to 1024 channels. However, as each stream can be programmed to a different data rate, any combination of data rates can be achieved, as long as the total channel count does not exceed 4096 channels. It should be noted that only full stream can be programmed for use. The device does not allow fractional streams.

4.1 External High Impedance Control, STOHZ0 - 15

There are 16 external high impedance control signals, STOHZ0 - 15, that are used to control the external drivers for per-channel high impedance operations. Only the first sixteen ST-BUS/GCI-Bus (STio0 - 15) outputs are provided with corresponding STOHZ signals. The STOHZ outputs deliver the appropriate number of control timeslot channels based on the output stream data rate. Each control timeslot lasts for one channel time. When the ODE pin is high and the OSB (bit 2) of the Control Register (CR) is also high, STOHZ0 - 15 are enabled. When the ODE pin, OSB (bit 2) of the Control Register (CR) or the RESET pin is low, STOHZ0 - 15 are driven high, together with all the ST-BUS/GCI-Bus outputs being tristated. Under normal operation, the corresponding STOHZ outputs of any

unused ST-BUS/GCI-Bus channel (high impedance) are driven high. Refer to Figure 18 on page 34 for a diagrammatical explanation.

4.2 Input Clock (CKi) and Input Frame Pulse (FPI) Timing

The input clock for the ZL50022 can be arranged in one of three different ways. These different ways will be explained further in Section 11.1 to Section 11.3 on page 39. Depending on the mode of operation, the input clock, CKi, will be based on the highest data rate of either the input or both the input and output data rates. The user has to program the CKIN1 - 0 (bits 6 - 5) in the Control Register (CR) to indicate the width of the input frame pulse and the frequency of the input clock supplied to the device.

In Master mode and Divided Slave mode, the input clock, CKi, must be at least twice the highest input or output data rate. For example, if the highest input data rate is 4.096 Mbps and the highest output data rate is 8.192 Mbps, the input clock, CKi, must be 16.384 MHz, which is twice the highest overall data rate. The only exception to this is for 16.384 Mbps input or output data. In this case, the input clock, CKi, is equal to the data rate. The input frame pulse, FPI, must always follow CKi.

In Master mode, CKo2 and FPo2 can be programmed to be used as CKi and FPI by setting CKi_LP (bit 10) in the Control Register (CR). This will internally loop back the CKo2 and FPo2 timing. When this bit is set, CKi and FPI must be tied low or high externally.

Highest <u>Input or Output</u> Data Rate	CKIN 1-0 Bits	Input Clock Rate (CKi)	Input Frame Pulse (FPI)
16.384 Mbps or 8.192 Mbps	00	16.384 MHz	8 kHz (61 ns wide pulse)
4.096 Mbps	01	8.192 MHz	8 kHz (122 ns wide pulse)
2.048 Mbps	10	4.096 MHz	8 kHz (244 ns wide pulse)

Table 1 - CKi and FPI Configurations for Master and Divided Slave Modes

In Multiplied Slave mode, the input clock, CKi, must be at least twice the highest input data rate, regardless of the output data rate. Following the example above, if the highest input data rate is 4.096 Mbps, the input clock, CKi, must be 8.192 MHz, regardless of the output data rate. The only exception to this is for 16.384 Mbps input data. In this case, the input clock, CKi, is equal to the data rate. The input frame pulse, FPI, must always follow CKi.

Highest <u>Input</u> Data Rate	CKIN 1-0 Bits	Input Clock Rate (CKi)	Input Frame Pulse (FPI)
16.384 Mbps or 8.192 Mbps	00	16.384 MHz	8 kHz (61 ns wide pulse)
4.096 Mbps	01	8.192 MHz	8 kHz (122 ns wide pulse)
2.048 Mbps	10	4.096 MHz	8 kHz (244 ns wide pulse)

Table 2 - CKi and FPI Configurations for Multiplied Slave Mode

The ZL50022 accepts positive and negative ST-BUS/GCI-Bus input clock and input frame pulse formats via the programming of CKINP (bit 8) and FPINP (bit 7) in the Control Register (CR). By default, the device accepts the negative input clock format and ST-BUS format frame pulses. However, the switch can also accept a positive-going clock format by programming CKINP (bit 8) in the Control Register (CR). A GCI-Bus format frame pulse can be used by programming FPINPOS (bit 9) and FPINP (bit 7) in the Control Register (CR).

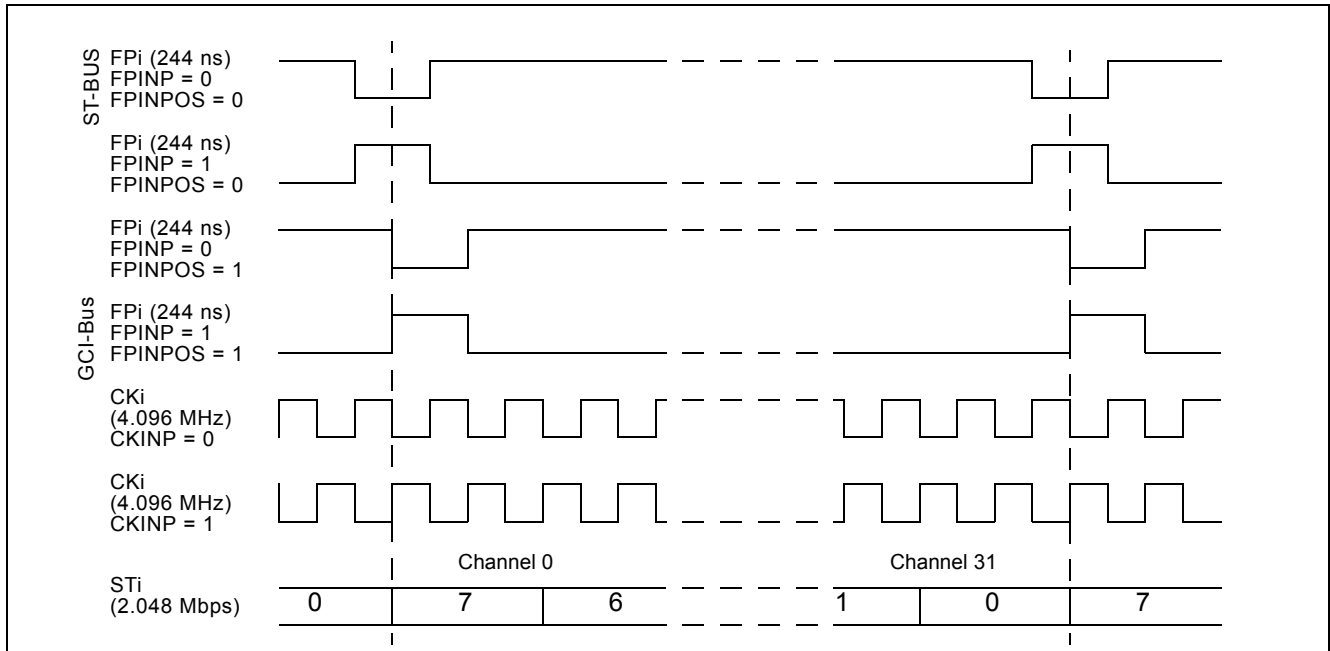

Figure 4 - Input Timing when CKIN1 - 0 bits = "10" in the CR

Figure 5 - Input Timing when CKIN1 - 0 bits = "01" in the CR

Figure 6 - Input Timing when CKIN1 - 0 = "00" in the CR

5.0 ST-BUS and GCI-Bus Timing

The ZL50022 is capable of operating using either the ST-BUS or GCI-Bus standards. The output timing that the device generates is defined by the bus standard. In the ST-BUS standard, the output frame boundary is defined by the falling edge of CKo while FPo is low. In the GCI-Bus standard, the frame boundary is defined by the rising edge of CKo while FPo goes high. The data rates define the number of channels that are available in a 125 μ s frame pulse period.

By default, the ZL50022 is configured for ST-BUS input and output timing. To set the input timing to conform to the GCI-Bus standard, FPINPOS (bit 9) and FPINP (bit 7) in the Control Register (CR) must be set. To set output timing to conform to the GCI-Bus standard, FPO[n]P and FPO[n]POS must be set in the Output Clock and Frame Pulse Selection Register (OCFSR). The CKO[n]P bits in the Output Clock and Frame Pulse Selection Register control the polarity (positive-going or negative-going) of the output clocks.

6.0 Output Timing Generation

The ZL50022 generates frame pulse and clock timing. There are five output frame pulse pins (FPo0 - 3, 5) and six output clock pins (CKo0 - 5). All output frame pulses are 8 kHz output signals. By default, the output frame boundary is defined by the falling edge of the CKo0, while FPo0 is low. At the output frame boundary, the CKo1, CKo2 and CKo3 output clocks will by default have a falling edge, while FPo1, FPo2 and FPo3 will be low. At the output frame boundary, CKo4 will by default have a falling edge while FPo0 is low (CKo4 has no corresponding output frame pulse). At the output frame boundary, CKo5 will by default have a rising edge while FPo5 (FPo_OFF2) will be low. The duration of the frame pulse low cycle and the frequency of the corresponding output clock are shown in Table 3 on page 25. Every frame pulse and clock output can be tristated by programming the enable bits in the Internal Mode Selection (IMS) register.

Pin Name	Output Timing Rate	Output Timing Unit
FPo0 pulse width	244	ns
CKo0	4.096	MHz
FPo1 pulse width	122	ns
CKo1	8.192	MHz
FPo2 pulse width	61	ns
CKo2	16.384	MHz
FPo3 pulse width	244, 122, 61 or 30	ns
CKo3	4.096, 8.192, 16.384 or 32.768	MHz
CKo4	1.544 or 2.048	MHz
FPo5 pulse width	51	ns
CKo5	19.44	MHz

Table 3 - Output Timing Generation

The output timing is dependent on the operation mode that is selected. When the device is in Divided Slave mode, the frequencies on CKo0 - 3 cannot be greater than the input clock, CKi. For example, if the input clock is 8.192 MHz, the CKo2 pin will not produce a valid output clock and the CKo3 pin can only be programmed to output a 4.096 MHz or 8.192 MHz clock signal. The output clocks CKo4 - 5 will not generate valid outputs unless the SLV_DPLEN (bit 13) of the Control Register (CR) is set.

In Master mode there are programmable output frame pulse, FPo3, and clock pins, CKo3 and CKo4. The outputs from FPo3 and CKo3 are programmed by the CKOFPO3SEL1 - 0 (bits 13 - 12) in the Output Clock and Frame Pulse Selection (OCFSR) register. The output clock pin, CKo4, is controlled by setting the CKO4SEL (bit 14) in the OCFSR register.

In Multiplied Slave mode, CKo4 and CKo5 are not available unless SLV_DPLEN is set in the Control Register. All other clocks and frame pulses correspond to the timing shown in Table 3 above.

The device also delivers positive or negative output frame pulse and ST-BUS/GCI-Bus output clock formats via the programming of various bits in the Output Clock and Frame Pulse Selection Register (OCFSR). By default, the device delivers the negative output clock format. The ZL50022 can also deliver GCI-Bus format output frame pulses by programming bits of the Output Clock and Frame Pulse Selection Register (OCFSR). As there is a separate bit setting for each frame pulse output, some of the outputs can be set to operate in ST-BUS mode and others in GCI-Bus mode.

The following figures describe the usage of the FPO0P, FPO1P, FPO2P, FPO3P, CKO0P, CKO1P, CKO2P, CKO3P, CKO4P and CKO5P bits to generate the FPo0 - 3 and CKo0 - 5 timing. FPo_OFF2 is configured to provide the non-offset frame pulse corresponding to the 19.44 MHz clock on CKo5 by setting the FP19EN (bit 10) in the FPOFF2 register. In this instance, FPo_OFF2 can be labeled as FPo5.

7.0 Data Input Delay and Data Output Advancement

Various registers are provided to adjust the input delay and output advancement for each input and output data stream. The input bit delay and output bit advancement can vary from 0 to 7 bits for each individual stream.

If input delay of less than a bit is desired, different sampling points can be used to handle the adjustments. The sampling point can vary from 1/4 to 4/4 with a 1/4-bit increment for all input streams, unless the stream is operating at 16.384 Mbps, in which case the fractional bit delay has a 1/2-bit increment. By default, the sampling point is set to the 3/4-bit location for non-16.384 Mbps data rates and the 1/2-bit location for the 16.384 Mbps data rate.

The fractional output bit advancement can vary from 0 to 3/4 bits, again with a 1/4-bit increment unless the output stream is operating at 16.384 Mbps, in which case the output bit advancement has a 1/2-bit increment from 0 to 1/2 bit. By default, there is 0 output bit advancement.

Although input delay or output advancement features are available on streams which are operating in bi-directional mode it is not recommended, as it can easily cause bus contention. If users require this function special, attention must be given to the timing to ensure contention is minimized.

7.1 Input Bit Delay Programming

The input bit delay programming feature provides users with the flexibility of handling different wire delays when designing with source streams for different devices.

By default, all input streams have zero bit delay, such that bit 7 is the first bit that appears after the input frame boundary (assuming ST-BUS formatting). The input delay is enabled by STIN[n]BD2-0 (bits 8 - 6) in the Stream Input Control Register 0 - 31 (SICR0 - 31) as described in Table 45 on page 79. The input bit delay can range from 0 to 7 bits.

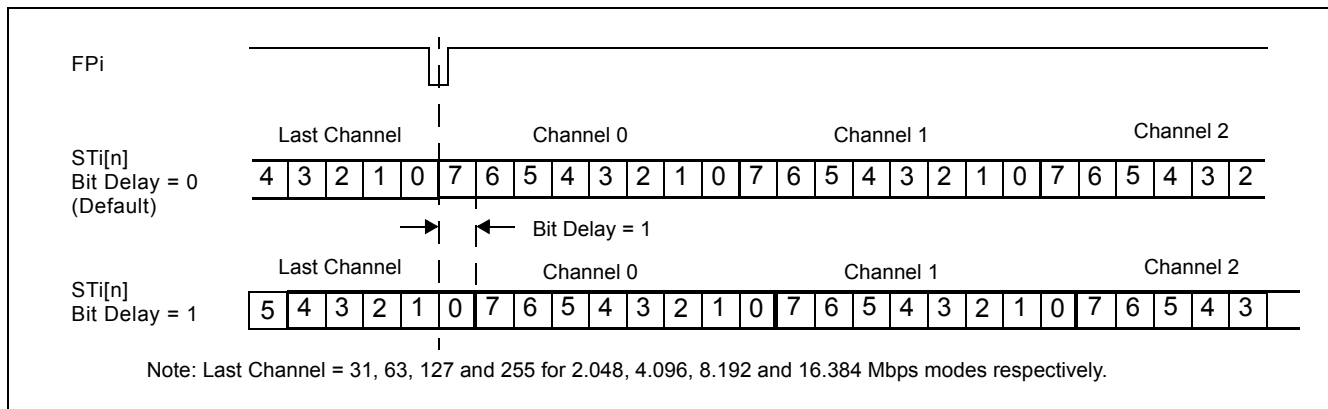

Figure 13 - Input Bit Delay Timing Diagram (ST-BUS)

7.2 Input Bit Sampling Point Programming

In addition to the input bit delay feature, the ZL50022 allows users to change the sampling point of the input bit by programming STIN[n]SMP 1-0 (bits 5 - 4) in the Stream Input Control Register 0 - 31 (SICR0 - 31). For input streams operating at any rate except 16.384 Mbps, the default sampling point is at 3/4 bit and users can change the sampling point to 1/4, 1/2, 3/4 or 4/4 bit position. When the stream is operating at 16.384 Mbps, the default sampling point is 1/2 bit and can be adjusted to a 4/4 bit position.

Figure 14 - Input Bit Sampling Point Programming

The input delay is controlled by STIN[n]BD2-0 (bits 8 - 6) to control the bit shift and STIN[n]SMP1 - 0 (bits 5 - 4) to control the sampling point in the Stream Input Control Register 0 - 31 (SICR0 - 31).

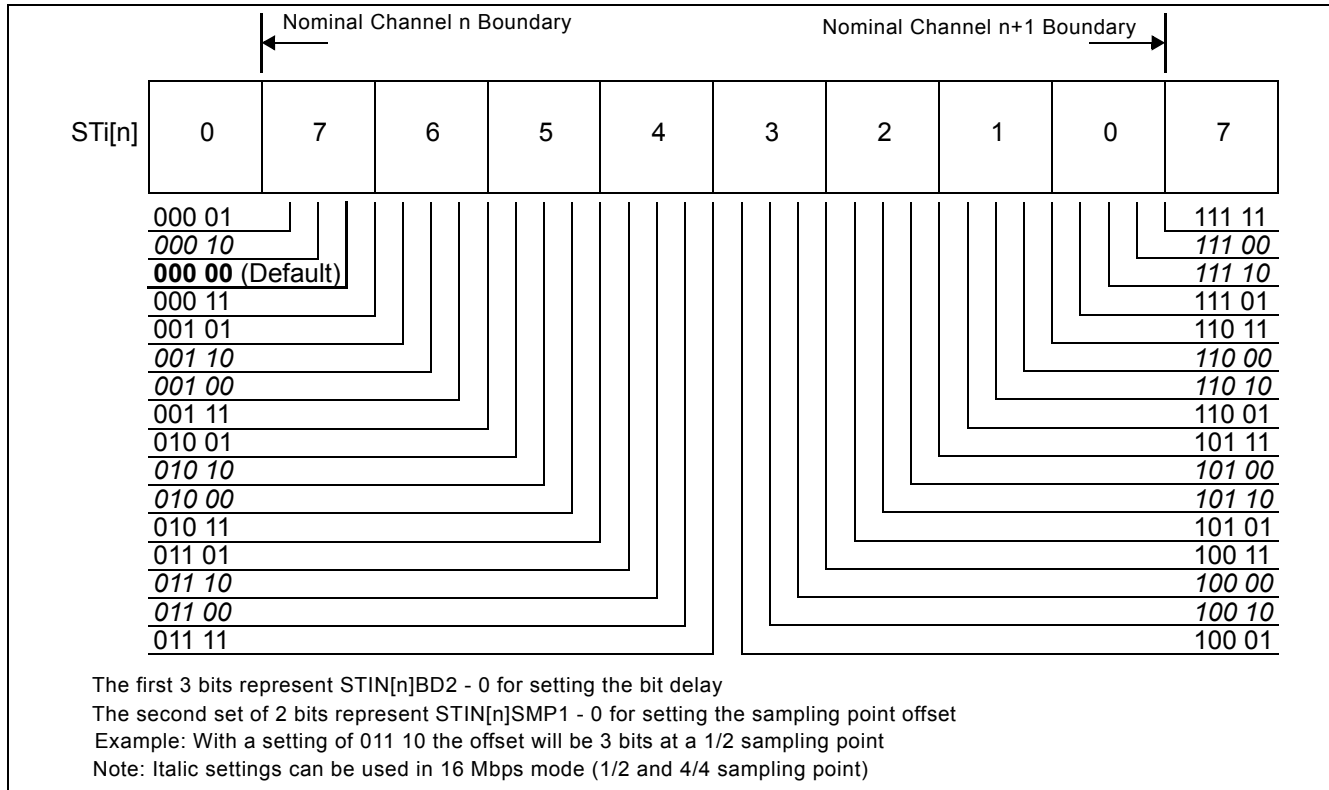

Figure 15 - Input Bit Delay and Fractional Sampling Point

7.3 Output Advancement Programming

This feature is used to advance the output data of individual output streams with respect to the output frame boundary. Each output stream has its own bit advancement value which can be programmed in the Stream Output Control Register 0 - 31 (SOCR0 - 31).

By default, all output streams have zero bit advancement such that bit 7 is the first bit that appears after the output frame boundary (assuming ST-BUS formatting). The output advancement is enabled by STIO[n]AD 2 - 0 (bits 6 - 4) of the Stream Output Control Register 0 - 31 (SOCR0 - 31) as described in Table 47 on page 83. The output bit advancement can vary from 0 to 7 bits.

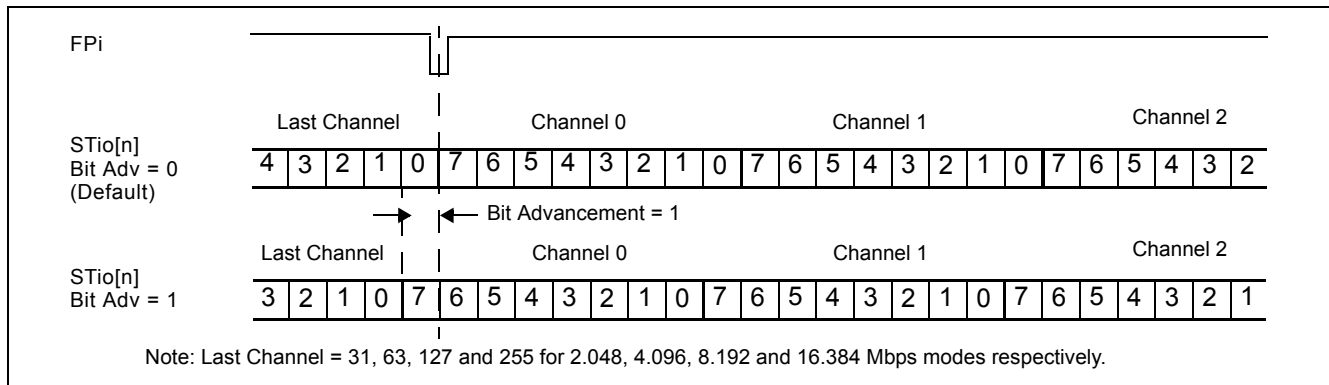

Figure 16 - Output Bit Advancement Timing Diagram (ST-BUS)

7.4 Fractional Output Bit Advancement Programming

In addition to the output bit advancement, the device has a fractional output bit advancement feature that offers better resolution. The fractional output bit advancement is useful in compensating for varying parasitic load on the serial data output pins.

By default all of the streams have zero fractional bit advancement such that bit 7 is the first bit that appears after the output frame boundary. The fractional output bit advancement is enabled by STIO[n]FA 1 - 0 (bits 8 - 7) in the Stream Output Control Register 0 - 31 (SOCR0 - 31). For all streams running at any data rate except 16.384 Mbps the fractional bit advancement can vary from 0, 1/4, 1/2 to 3/4 bits. For streams operating at 16.384 Mbps, the fractional bit advancement can be set to either 0 or 1/2 bit.

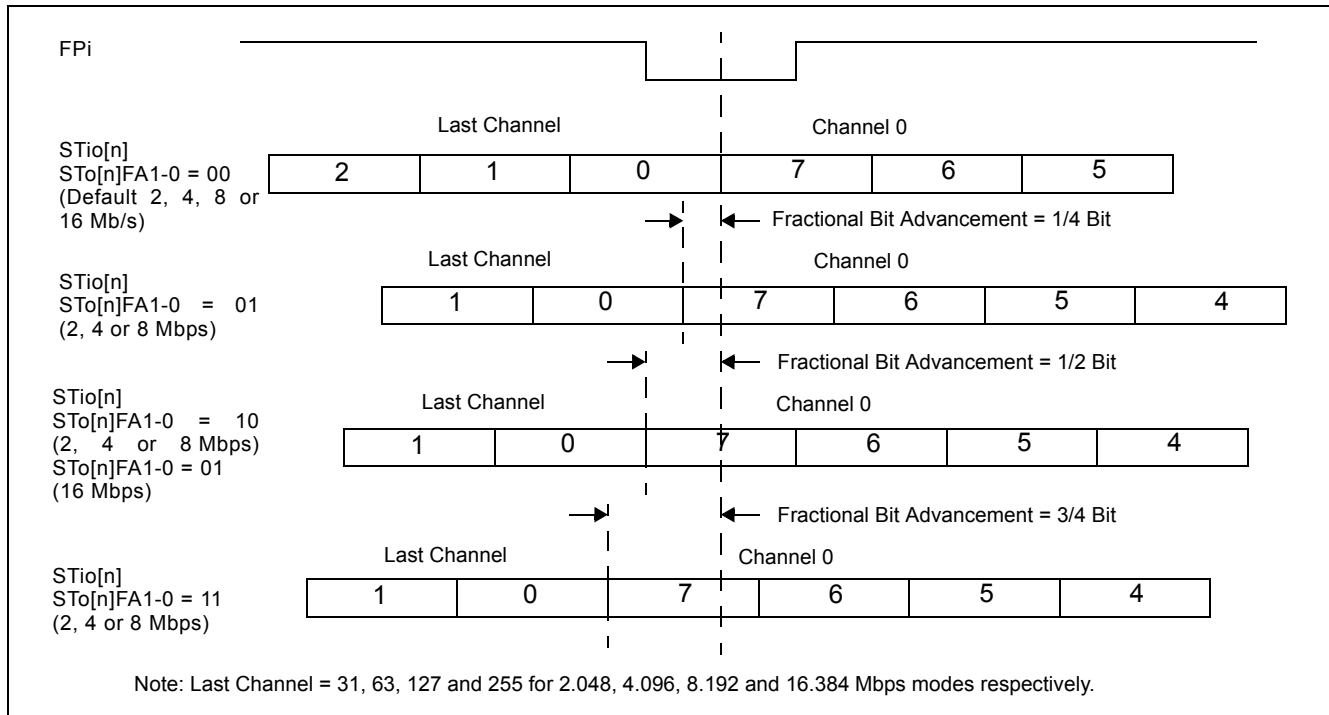

Figure 17 - Output Fractional Bit Advancement Timing Diagram (ST-BUS)

7.5 External High Impedance Control Advancement

The external high impedance signals can be programmed to better match the timing required by the external buffers. By default, the output timing of the STOHZ signals follows the programmed channel delay and bit offset of their corresponding ST-BUS/GCI-Bus output streams. In addition, for all high impedance streams operating at any data rate except 16.384 Mbps, the user can advance the STOHZ signals a further 0, 1/4, 1/2, 3/4 or 4/4 bits by programming STOHZ[n]A 2 - 0 (bit 11 - 9) in the Stream Output Control Register. When the stream is operating at 16.384 Mbps, the additional STOHZ advancement can be set to 0, 1/2 or 4/4 bits by programming the same register.

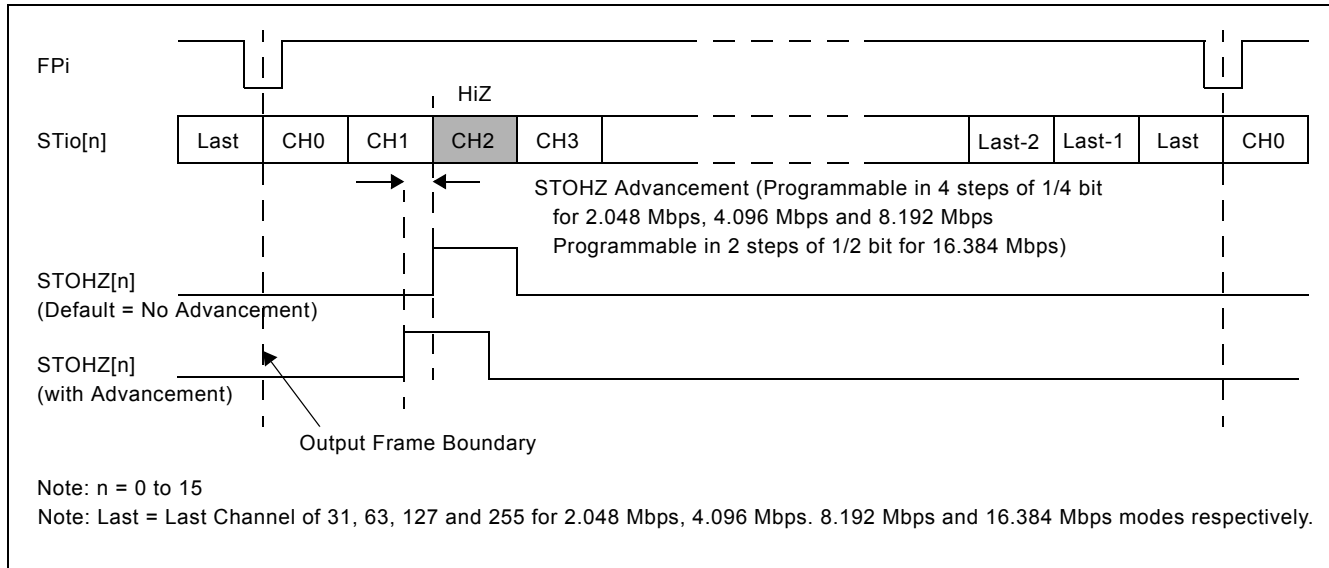

Figure 18 - Channel Switching External High Impedance Control Timing

8.0 Data Delay Through the Switching Paths

The switching of information from the input serial streams to the output serial streams results in a throughput delay. The device can be programmed to perform timeslot interchange functions with different throughput delay capabilities on a per-channel basis. For voice applications, select variable throughput delay to ensure minimum delay between input and output data. In wideband data applications, select constant delay to maintain the frame integrity of the information through the switch. The delay through the device varies according to the type of throughput delay selected by the $\overline{V/C}$ (bit 14) in the Connection Memory Low when CMM = 0.

8.1 Variable Delay Mode

Variable delay mode causes the output channel to be transmitted as soon as possible. This is a useful mode for voice applications where the minimum throughput delay is more important than frame integrity. The delay through the switch can vary from 7 channels to 1 frame + 7 channels. To set the device into variable delay mode, VAREN (bit 4) in the Control Register (CR) must be set before $\overline{V/C}$ (bit 14) in the Connection Memory Low when CMM = 0. If the VAREN bit is not set and the device is programmed for variable delay mode, the information read on the output stream will not be valid.

In variable delay mode, the delay depends on the combination of the source and destination channels of the input and output streams.

m = input channel number n = output channel number	n-m <= 0	0 < n-m < 7	n-m = 7		n-m > 7
			STio < STi	STio >= STi	
T = Delay between input and output	1 frame - (m-n)	1 frame + (n-m)	n-m		

Table 4 - Delay for Variable Delay Mode

For example, if Stream 4 Channel 2 is switched to Stream 5 Channel 9 with variable delay, the data will be output in the same 125 μs frame. Contrarily, if Stream 6 Channel 1 is switched to Stream 9 Channel 3, the information will appear in the following frame.

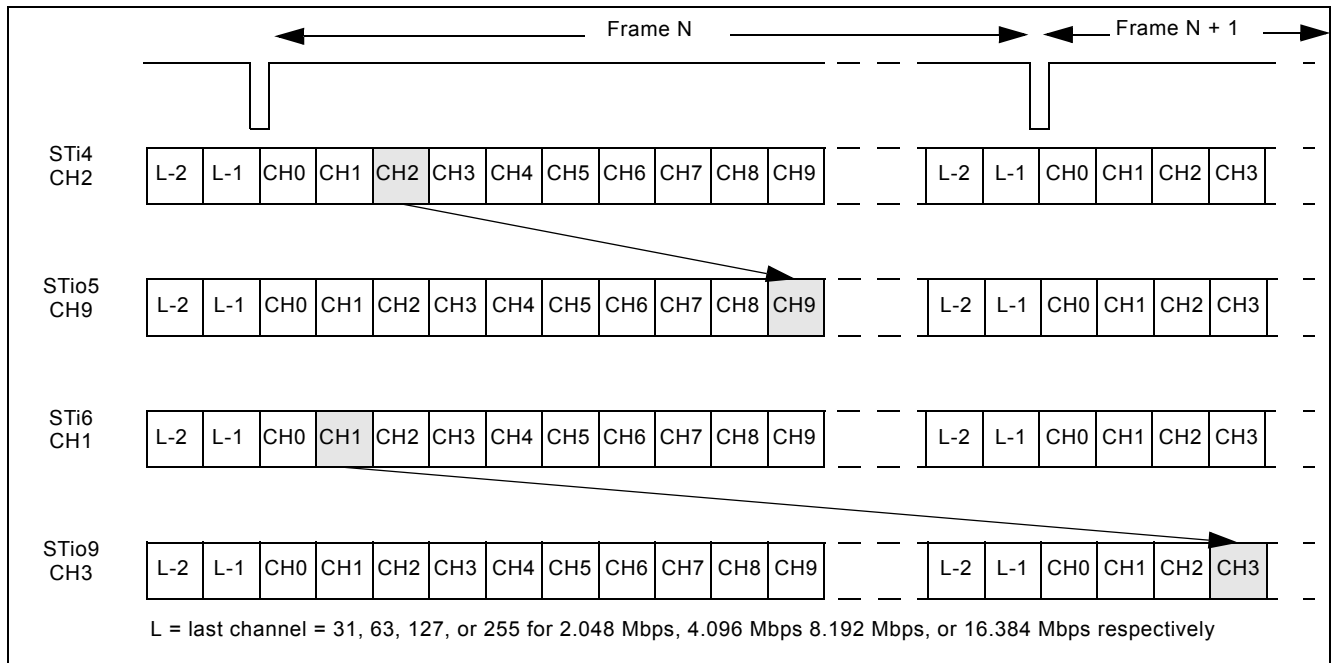

Figure 19 - Data Throughput Delay for Variable Delay

8.2 Constant Delay Mode

In this mode, frame integrity is maintained in all switching configurations. The delay through the switch is 2 frames - Input Channel + Output Channel. This can result in a minimum of 1 frame + 1 channel delay if the last channel on a stream is switched to the first channel of a stream. The maximum delay is 3 frames - 1 channel. This occurs when the first channel of a stream is switched to the last channel of a stream. The constant delay mode is available for all output channels.

The data throughput delay is expressed as a function of ST-BUS/GCI-Bus frames, input channel number (m) and output channel number (n). The data throughput delay (T) is:

$$T = 2 \text{ frames} + (n - m)$$

The constant delay mode is controlled by $\sqrt{V/C}$ (bit 14) in the Connection Memory Low when CMM = 0. When this bit is set low, the channel is in constant delay mode. If VAREN (bit 4) in the Control Register (CR) is set (to enable variable throughput delay on a chip-wide basis), the device can still be programmed to operate in constant delay mode.

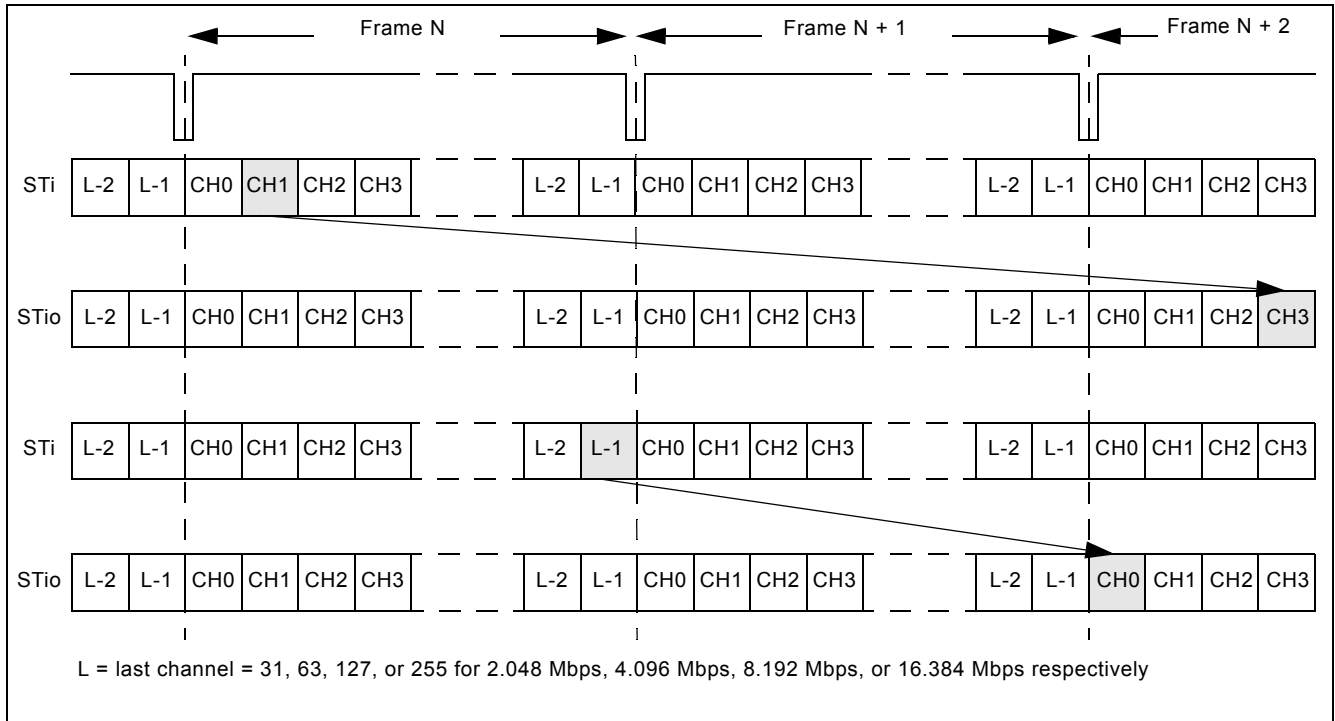

Figure 20 - Data Throughput Delay for Constant Delay

9.0 Connection Memory Description

The connection memory consists of two blocks, Connection Memory Low (CM_L) and Connection Memory High (CM_H). The CM_L is 16-bits wide and is used for channel switching and other special modes. The CM_H is 5 bits wide and is used for the voice coding function. When UAEN (bit 15) of the Connection Memory Low (CM_L) is low, μ -law/A-law conversion will be turned off and the contents of CM_H will be ignored. Each connection memory location of the CM_L or CM_H can be read or written via the 16-bit microprocessor port within one microprocessor access cycle. See Table 52 on page 86 for the address mapping of the connection memory. Any unused bits will be reset to zero on the 16-bit data bus.

For the normal channel switching operation, CMM (bit 0) of the Connection Memory Low (CM_L) is programmed low. SCA7 - 0 (bits 8 - 1) indicate the source (input) channel address and SSA4 - 0 (bits 13 - 9) indicate the source (input) stream address. The 5-bit contents of the CM_H will be ignored during the normal channel switching mode without the μ -law/A-law conversion when UAEN (bit 15) of the Connection Memory Low (CM_L) is set to zero. If μ -law/A-law conversion is required, the CM_H bits must be programmed first to provide the voice/data information, the input coding law and the output coding law before the assertion of UAEN (bit 15) in the Connection Memory Low.

When CMM (bit 0) of the Connection Memory Low (CM_L) is programmed high, the ZL50022 will operate in one of the special modes described in Table 54 on page 88. When the per-channel message mode is enabled, MSG7 - 0 (bit 10 - 3) in the Connection Memory Low (CM_L) will be output via the serial data stream as message output data. When the per-channel message mode is enabled, the μ -law/A-law conversion can also be enabled as required.

10.0 Connection Memory Block Programming

This feature allows for fast initialization of the connection memory after power up.

10.1 Memory Block Programming Procedure

1. Set MBPE (bit 3) in the Control Register (CR) from low to high.
2. Configure BPD2 - 0 (bits 3 - 1) in the Internal Mode Selection (IMS) register to the desired values to be loaded into CM_L.
3. Start the block programming by setting MBPS (bit 0) in the Internal Mode Selection Register (IMS) high. The values stored in BPD2 - 0 will be loaded into bits 2 - 0 of all CM_L positions. The remaining CM_L locations (bits 15 - 3) and the programmable values in the CM_H (bits 4 - 0) will be loaded with zero values.

The following tables show the resulting values that are in the CM_L and CM_H connection memory locations.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Value	0	0	0	0	0	0	0	0	0	0	0	0	0	BPD2	BPD1	BPD0

Table 5 - Connection Memory Low After Block Programming

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 6 - Connection Memory High After Block Programming

Note: Bits 15 to 5 are reserved in Connection Memory High and should always be 0.

It takes at least two frame periods (250 μ s) to complete a block program cycle.

MBPS (bit 0) in the Control Register (CR) will automatically reset to a low position after the block programming process has completed.

MBPE (bit 3) in the Internal Mode Selection (IMS) register must be cleared from high to low to terminate the block programming process. This is not an automatic action taken by the device and must be performed manually.

Note: Once the block program has been initiated, it can be terminated at any time prior to completion by setting MBPS (bit 0) in the Control Register (CR) or MBPE (bit 3) in the Internal Mode Selection (IMS) register to low. If the MBPE bit was used to terminate the block programming, the MBPS bit will have to be set low before enabling other device operations.

11.0 Device Operation in Master Mode and Slave Modes

This device has two main operating modes - Master mode and Slave mode. Each operating mode has different input/output clock and frame pulse setup requirements and usage.

If the device is programmed to work in Master mode, it is expected that the input clock and frame pulse will be supplied from the embedded DPLL, either directly using the internal loopback mode or indirectly through external loopback path. Sources and destinations of the device's serial input and output data, respectively, have to be synchronized with the device's output clock and frame pulse. In Master mode, output clocks and frame pulses are driven by the DPLL and they are always available with any of the specified frequencies.

The device can also operate in two different Slave modes: Divided Slave mode and Multiplied Slave mode. In either Slave modes, output clocks and frame pulses are generated based on CKi and FPI. The difference is that, in

Divided Slave mode, the output clocks and frame pulses are directly divided from CKi/FPi, while in Multiplied Slave mode, the output clocks and frame pulses are generated from an internal high-speed clock synchronized to CKi and FPi. Therefore, in Divided Slave mode, the output clock rates cannot exceed the CKi rate (the output data rates are also limited as per Table 1), but in Multiplied Slave mode, all specified output clock rates and data rates are available on CKo0-3 and STio0-31. The input data rate cannot exceed the CKi rate in either Slave modes, because input data are always sampled directly by CKi.

By default, CKo4, CKo5 and FPo5 are not available in Slave mode, as the embedded DPLL is disabled. However, the DPLL can be activated even in Slave mode by programming the SLV_DPLEN bit in the Control Register. When the DPLL is enabled in Slave mode, CKo4, CKo5 and FPo5 are generated from the DPLL synchronized to one of the REF0-3 inputs, while the other clocks, frame pulses, and input/output data are synchronized to CKi/FPi. It basically creates two separate timing domains - one for the DPLL, and one for data switch logic. The two can be totally asynchronous to each other. In this case the DPLL will be fully functional, including its capability of reference monitoring.

Note that an external oscillator is required whenever the DPLL is used.

Table 7, “ZL50022 Operating Modes” on page 38 summarizes the different modes of operation available within the ZL50022. Each Major mode has various associated Minor modes that are determined by setting the relevant Input Control pins and Control Register bits (Table 17, “Control Register (CR) Bits” on page 53) indicated in the table.

Device		Input Pins				CR Register			Output Clock Pins				Data Pins		
Operating Mode		Control		Signal		Bits			Reference Lock		Enabled		Clock Source		
Major	Minor	OSC_EN	MODE_4M [1:0]	OSCi	CKi	OPM [1:0]	SLV_DPLEN	CKi_LP	CKo0-3	CKo4-5	CKo0-3	CKo4-5	STi	STo	
Master	CKi	1	00	20 MHz	4/8/16 M	00	X	0	Freerun, Holdover or REF0-3		Yes	Yes	CKi*	CKo2 (DPLL)	
	Loopback				X			1					Cko2		
Divided Slave	4 M	1	11	20 MHz	4 M	01	1	X	CKi	REF0-3			Yes	CKi	CKo0-3 (CKi)
	8/16 M		00		8/16 M										
	4 M	0	11	X	4 M	X0	0		X				No		
	8/16 M		00	8/16 M											
Multiplied Slave	4 M	1	11	20 MHz	4 M	11	1		CKi MULT	REF0-3			Yes		CKo0-3 (CKi MULT)
	8/16 M		00		8/16 M										
	4 M	0	11	X	4 M	X1	0		X				No		
	8/16 M		00	8/16 M											

Legend:

X - Don't care or not applicable.

Reference Lock - Refers to what signal the output pins are locked to:
REF0-3 = Normal Mode
Cki = Bypass. Cki is passed directly through to CKo0-3.
CKi MULT = Cki is passed through clock multiplier to CKo0-3.
* CKi must be phase aligned (edge synchronous) to CKo0-3.
Clock Source - Refers to which clock samples STi and which clock outputs STo; STi applies when STi or STio is input; STo applies when STio is output.

Table 7 - ZL50022 Operating Modes

11.1 Master Mode Operation

When the device is in Master mode, the DPLL is phase-locked to the one of four DPLL reference signals, REF0 to REF3, which are sourced by an external 8 kHz, 1.544 MHz, 2.048 MHz, 4.096 MHz, 8.192 MHz, 16.384 MHz or 19.44 MHz signal. The on-chip DPLL also offers reference switching and monitoring, jitter attenuation, freerun and holdover functions. In this mode, STio0 - 31 are driven by a clock generated by the DPLL, which also provides all the output clocks (CKo0 - 5) and frame pulses (FPo0 - 3 and FPo_OFF0 - 2). One of the output clocks and frame pulses should be looped back to CKi/FPi as reference for the input data, either by internal loopback (by setting the CKi_LP bit high in the Control Register) or through some external loopback paths. If external loopback is used, it is recommended that CKo2 (16.384MHz) and FPo2 (61ns pulse) are used so that all input data rates are available.

11.2 Divided Slave Mode Operation

When the device is in Divided Slave mode, STio0 - 31 are driven by CKi. In this mode, the output streams and clocks have the same jitter characteristics as the input clock (CKi), but the input and output data rates cannot exceed the limit defined by CKi (as per Table 1). For example, if CKi is 4.096 MHz, the input and output data rate cannot be higher than 2.048 Mbps, and the generated output clock rates cannot exceed 4.096 MHz. If the DPLL is not enabled, an external oscillator is optional in Divided Slave mode.

11.3 Multiplied Slave Mode Operation

When the device is in Multiplied Slave mode, device hardware is used to multiply CKi internally. STio0 - 31 are driven by this internally generated clock. In this mode, the output clocks and data can run at any of the specified rates, but they may have different jitter characteristics from the input clock (CKi). The input data rates are still limited by the CKi rate (as per Table 1), as input data are always sampled directly by CKi. If the DPLL is not enabled, an external oscillator is not required in Multiplied Slave mode.

12.0 Overall Operation of the DPLL

The DPLL accepts four input references and delivers six output clocks and five output frame pulses. The DPLL meets or exceeds all of the requirements of the Telcordia GR-1244-CORE standard for a Stratum 4E compliant PLL. This includes the freerun, reference switching and monitoring, jitter/wander attenuation and holdover functions. The intrinsic output jitter of the DPLL does not exceed 1 ns (except for the 1.544 MHz output).

The DPLL is able to lock to an input reference presented on the REF0 - 3 inputs. It is possible to force the DPLL module to lock to a selected reference, to prefer one reference, to enter holdover mode or to freerun.

12.1 DPLL Timing Modes

There are four timing modes for the DPLL: normal, holdover, automatic and freerun modes. In addition to these four functional timing modes, the DPLL can also be programmed to internal reset mode.

12.1.1 Normal Mode

In normal timing mode, the DPLL generates clocks and frame pulses that are phase locked to the active input reference. Jitter on the input clock is attenuated by the DPLL.

12.1.2 Holdover Mode

In holdover mode, the DPLL no longer synchronizes the output clock to any input reference. It maintains the frequency that it was at prior to entering holdover mode. The holdover mode typically happens when the input clock becomes unreliable or is lost altogether. It takes some time for the system to realize that the input clock is unreliable. Meanwhile, the DPLL tracks an unreliable clock. Therefore the DPLL could hold to an invalid frequency when it enters holdover mode. In order to prevent this situation, the DPLL stores the current frequency at regular intervals in holdover memory so that it can restore the frequency of the input clock just after the input clock became unreliable.

12.1.3 Automatic Mode

In this mode, the state machine controls the DPLL based on the settings in the registers and the quality of the reference input clocks. The DPLL is internally either in normal or holdover mode. In the following two sections, the reference selection and state machine operation in automatic mode will be explained in more details.

12.1.3.1 Automatic Reference Switching Without Preferences

When the DPLL is programmed to operate in Automatic mode without Preference (RCCR Register, PMS2-0 bits = 000), all references, REF0-3, will have equal importance. A circulating *Round Robin* selection sequence determines the reference to be used as shown in Figure 21. The state machine basically searches for valid reference in a circular order of REF0 -> REF1 -> REF2 -> REF3 -> REF0, etc.

Figure 21 - Automatic Reference Switching State Diagram with No Preferred Reference

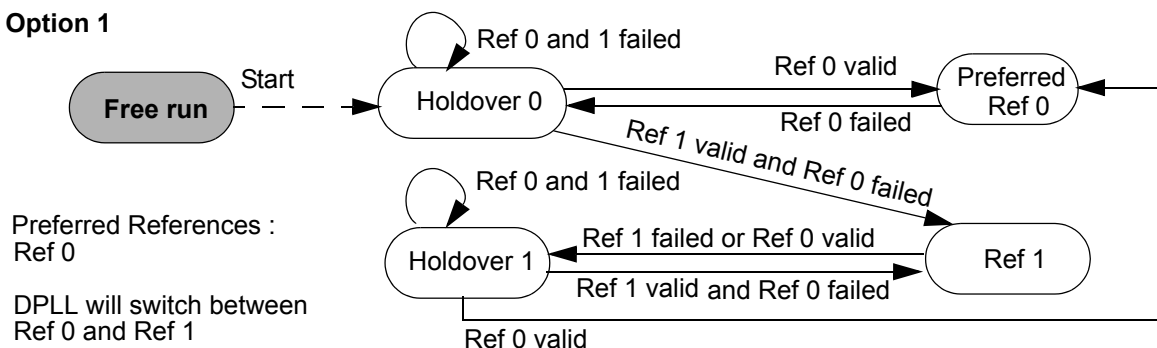

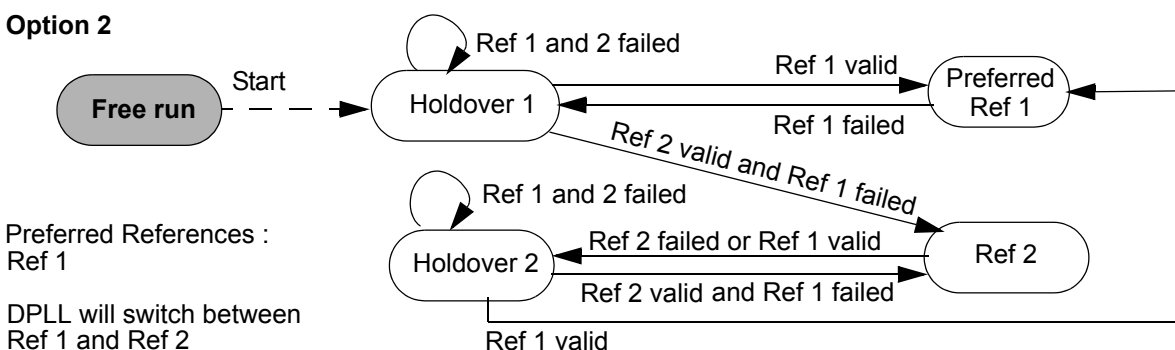

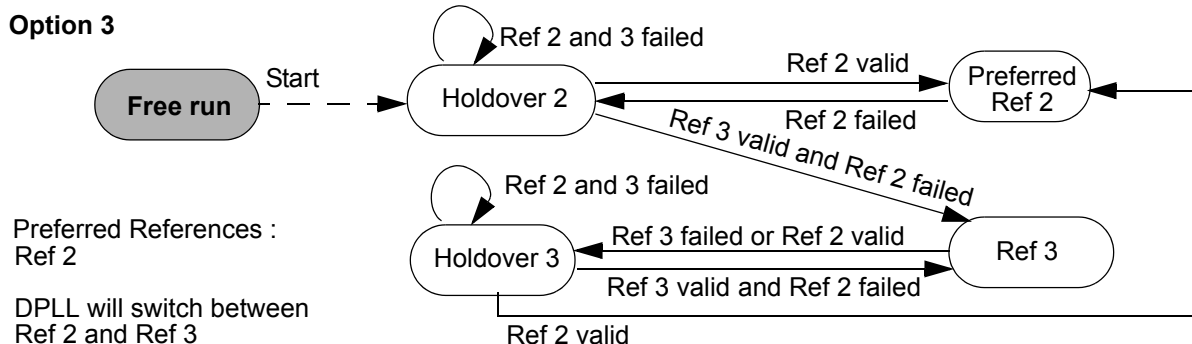

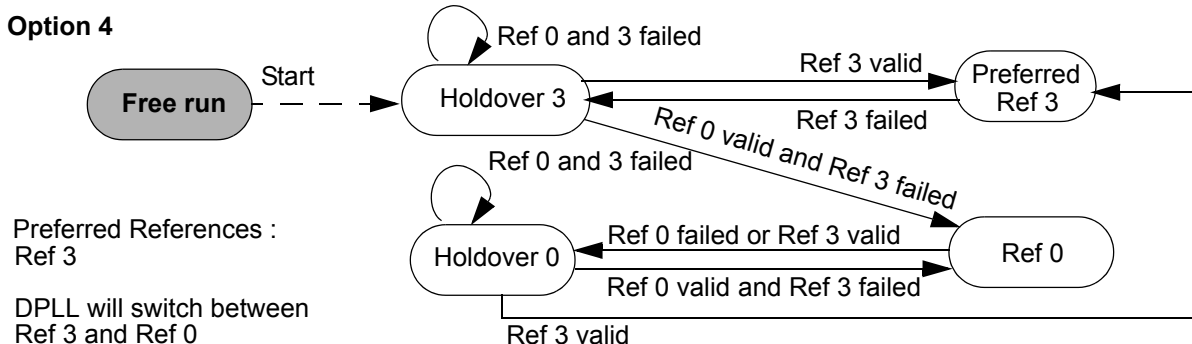

12.1.3.2 Automatic Reference Switching With Preferences

If a particular reference needs to have higher priority than the others, the device can be programmed in Automatic mode with a preferred reference (RCCR Register, PMS2-0 bits = 001). When a preferred reference is selected, the device can only switch automatically between two references, as shown in Table 8. The preferred reference will be used as the primary reference and, by default, only its next consecutive reference will be used as the secondary reference. No more than two references can be used in Automatic mode when a preferred reference is selected.

	Primary Reference (Preferred)	Secondary Reference
Option 1	Ref 0	Ref 1
Option 2	Ref 1	Ref 2
Option 3	Ref 2	Ref 3
Option 4	Ref 3	Ref 0

Table 8 - Preferred Reference Selection Options

Figure 22 shows the state diagram for the four valid options of automatic reference switching with a preferred reference.

Option 1**Option 2****Option 3****Option 4**

Note : other combinations not shown here are invalid settings and should not be used

Figure 22 - Automatic Reference Switching State Diagrams with Preferred Reference

With a preferred reference, if more than two references are required, or the two references are not in consecutive order, or the roles of the two references need to be interchanged, then external software is required to manually control the reference switching of the DPLL (by monitoring the reference failure status and reprogramming the device accordingly).

12.1.4 Freerun Mode

In freerun mode, the DPLL generates a fixed output frequency based on the crystal oscillator frequency. To meet Stratum 4E, the accuracy of the circuitry for the freerunning output clock must be ± 32 ppm or better.

12.1.5 DPLL Internal Reset Mode

DPLL_IRM (bit 0) in the DPLL Control Register (DPLLCR) enables the internal reset mode. In the internal reset mode, the DPLL module is disabled to save power. The circuit will be reset continuously and no output clocks will be generated. When the internal DPLL module is in the internal reset mode, all registers remain accessible. Note that applying the DPLL reset does not reset the DPLL registers: they preserve the values that they had prior to entering reset.

13.0 DPLL Frequency Behaviour

13.1 Input Frequencies

The DPLL is able to synchronize to one of the following input frequencies:

8 kHz
1.544 MHz (DS1)
2.048 MHz (E1)
4.096 MHz
8.192 MHz
16.384 MHz
19.44 MHz

Table 9 - DPLL Input Reference Frequencies

13.2 Input Frequencies Selection

The input frequencies of REF 0 - 3 can be automatically detected or programmed independently by the Reference Frequency Register (RFR) if RFRE (bit 1) in the DPLL Control Register (DPLLCR) is set. The detected frequency of the selected reference is indicated in the Reference Change Status Register (RCSR). In addition, the detected frequencies of all four references are indicated in the Reference Frequency Status Register (RFSR). See Table 28 on page 63, Table 29 on page 64, Table 37 on page 70 and Table 43 on page 77 for the detailed bit description of the DPLL Control Register (DPLLCR), Reference Frequency Register (RFR), Reference Change Status Register (RCSR) and Reference Frequency Status Register (RFSR), respectively.

13.3 Output Frequencies

The DPLL generates a limited number of output signals. All signals are synchronous to each other and in the normal operating mode, are locked to the selected input reference. The DPLL provides outputs with the following frequencies:

CKo0	4.096 MHz
CKo1	8.192 MHz
CKo2	16.384 MHz
CKo3	4.096 MHz, 8.192 MHz, 16.384 MHz or 32.768 MHz
CKo4	1.544 MHz or 2.048 MHz
CKo5	19.44 MHz
FPo0	8 kHz (244 ns wide pulse)
FPo1	8 kHz (122 ns wide pulse)
FPo2	8 kHz (61 ns wide pulse)
FPo3	8 kHz (244 ns, 122 ns, 61 ns or 30 ns wide pulse)
FPo5	8 kHz (51 ns wide pulse)

Table 10 - Generated Output Frequencies

13.4 Pull-In/Hold-In Range (also called Locking Range)

The widest tolerance required for any of the given input clock frequencies is ± 130 ppm for the T1 clock (1.544 MHz). If the system clock (crystal/oscillator) accuracy is ± 30 ppm, it requires a minimum pull-in range of ± 160 ppm. Users who do not require the ± 30 ppm freerun accuracy of the DPLL can use a ± 100 ppm system clock. Therefore the pull-in range is a minimal ± 230 ppm. The pull-in range of this device is ± 260 ppm.

14.0 Jitter Performance

14.1 Input Clock Cycle to Cycle Timing Variation Tolerance

The ZL50022 has an exceptional cycle to cycle timing variation tolerance of 20 ns. This allows the ZL50022 to synchronize off a low cost DPLL when it is in either Divided Slave mode or Multiplied Slave mode.

14.2 Input Jitter Acceptance

The input jitter acceptance is specified in standards as the minimum amount of jitter of a certain frequency on the input clock that the DPLL must accept without making cycle slips or losing lock. The lower the jitter frequency, the larger the jitter acceptance. For jitter frequencies below a tenth of the cut-off frequency of the DPLL's jitter transfer function, any input jitter will be followed by the DPLL. The maximum value of jitter tolerance for the DPLL is $\pm 1023 U_{I_{p-p}}$.

14.3 Jitter Transfer Function

The corner frequency (-3 dB) of the Stratum 4E DPLL is 15.2 Hz.

15.0 DPLL Specific Functions and Requirements

15.1 Lock Detector

To determine if the DPLL is locked to the input clock, a lock detector monitors the phase value output of the phase detector, which represents the difference between input reference and output feedback clock. If the phase value is below a certain threshold for a certain interval, the DPLL is pronounced locked to the input clock. The monitoring is done in intervals of 4 ms. The lock detector threshold and the interval are programmable by the user through the Lock Detector Threshold Register (LDTR) and the Lock Detector Interval Register (LDIR) respectively. See Table 33 on page 67 and Table 34 on page 68 for the bit descriptions of the Lock Detector Threshold Register (LDTR) and Lock Detector Interval Register (LDIR) respectively. The value of the Lock Detector Threshold Register

(LDTR) should be programmed with respect to the maximum expected jitter frequency and amplitude on the selected input references.

The lock status can be monitored through the Reference Change Status Register (RCSR). See Table 37 on page 70 for the bit description of the Reference Change Status Register (RCSR).

15.2 Maximum Time Interval Error (MTIE)

Several standards require that the output clock of the DPLL may not move in phase more than a certain amount. In order to meet those standards, a special circuit maintains the phase of the DPLL output clock during reference and mode rearrangements. The total output phase change or Maximum Timing Interval Error (MTIE) during rearrangements is less than 31 ns per rearrangement, exceeding Stratum 4E requirements. After a large number of reference switches, the accumulated phase error can become significant, so it is recommended to use MTIE reset in such situations, to realign outputs to the nearest edge of the selected reference. The MTIE reset can be programmed by setting MTR (bit 7) in the Reference Change Control Register (RCCR), as described in Table 36 on page 69.

15.3 Phase Alignment Speed (Phase Slope)

Besides total phase change, standards also require a certain rate of the phase change of the output clock. The phase alignment speed is programmable by the user through a value in the Slew Rate Limit Register (SRLR) as described in Table 35 on page 68. Stratum 4E requires that the phase alignment speed not exceed 81 ns per 1.326 ms (61ppm). The width of the register and the limiter circuitry provide a maximum phase change alignment speed of 186 ppm. The phase alignment speed default value is 56 ppm.

15.4 Reference Monitoring

The quality of the four input reference clocks is continuously monitored by the reference monitors. There are separate reference monitor circuits for the four DPLL references. References are checked for short phase (single period) deviations as well as for frequency (multi-period) deviations with hysteresis.

The Reference Status Register (RSR) reports the status of the reference monitors. The register bits are described in Table 41 on page 74. The Reference Mask Register (RMR) allows users to ignore the monitoring features of the reference monitors. See Table 42 on page 75 for details.

15.5 Single Period Reference Monitoring

Values for short phase deviations (upper and lower limit) are programmable through registers. The unit of the binary values of these numbers is 100 MHz clock period (10 ns). Single period deviation limits are more relaxed than multi period limits, and are used for early detection of the reference loss, or huge phase jumps.

The values for the upper and lower limits are shown in the following table:

Reference Frequency	Comment
8 kHz	10UIp-p
1.544 MHz	0.3UIp-p
2.048 MHz	0.2UIp-p
4.096 MHz	0.2UIp-p
8.192 MHz	0.2UIp-p
16.384 MHz	0.2UIp-p
19.44 MHz	0.2UIp-p

Table 11 - Values for Single Period Limits

15.6 Multiple Period Reference Monitoring

To monitor reference failure based on frequency offset, multi-period checking is performed. Reference validation time is prescribed by Telcordia GR-1244-CORE and is between 10 and 30 seconds. To meet the criteria for reference validation time, the time base for multi period monitoring has to be big enough. To implement hysteresis, the upper limits are split into near upper and far upper limits and the lower limits are split into near lower and far lower limits. The reference failure is detectable only when the reference passes far limits, but passing is not detected until the reference is within near limits. The zone between near and far limits, called the “grey zone”, is required by standards and prevents unnecessary reference switching when the selected reference is close to the boundary of failure.

The monitor makes a decision about reference validity after two consecutive measurements with respect to its time base. The time base for multi-period monitoring is 10 seconds. The time base is defined in the number of reference clock cycles.

The device has two sets of limits, the Stratum 4E default limits and the Relaxed Stratum 4E limits (see Table 12, “Multi-period Hysteresis Limits” on page 46). The ST4_LIM bit in Table 28, DPLL Control Register (DPLLCR) Bits is used to select between the two sets of limits.

	Stratum 4E Default Limits (in 10 ns units)	Relaxed Stratum 4E Limits (in 10 ns units)
Far Upper Limit	-82.487 ppm	-250 ppm
Near Upper Limit	-64.713 ppm	-240 ppm
Nominal Value	0 ppm	
Near Lower Limit	64.713 ppm	240 ppm
Far Lower Limit	82.487 ppm	250 ppm

Table 12 - Multi-period Hysteresis Limits

16.0 Microprocessor Port

The device provides access to the internal registers, connection memories and data memories via the microprocessor port. The microprocessor port is capable of supporting both Motorola and Intel non-multiplexed microprocessors. The microprocessor port consists of a 16-bit parallel data bus (D15 - 0), 14 bit address bus (A13 - 0) and six control signals (MOT_INTEL, CS, DS_RD, R/W_WR, IRQ and DTA_RDY).

The data memory can only be read from the microprocessor port. For a data memory read operation, D7 - 0 will be used and D15 - 8 will output zeros.

For a CM_L read or write operation, all bits (D15 - 0) of the data bus will be used. For a CM_H write operation, D4 - 0 of the data bus must be configured and D15 - 5 are ignored. D15 - 5 must be driven either high or low. For a CM_H read operation, D4 - 0 will be used and D15 - 5 will output zeros.

Refer to Figure 26 on page 94, Figure 27 on page 95, Figure 28 on page 96 and Figure 29 on page 97 for the microprocessor timing.

17.0 Device Reset and Initialization

The RESET pin is used to reset the ZL50022. When this pin is low, the following functions are performed:

- synchronously puts the microprocessor port in a reset state
- tristates the STio0 - 31 outputs
- drives the STOHZ0 - 15 outputs to high

- preloads all internal registers with their default values (refer to the individual registers for default values)
- clears all internal counters

17.1 Power-up Sequence

The recommended power-up sequence is for the V_{DD_IO} supply (normally +3.3 V) to be established before the power-up of the V_{DD_CORE} supply (normally +1.8 V). The V_{DD_CORE} supply may be powered up at the same time as V_{DD_IO} , but should not “lead” the V_{DD_IO} supply by more than 0.3 V.

17.2 Device Initialization on Reset

Upon power up, the ZL50022 should be initialized as follows:

- Set the ODE pin to low to disable the STio0 - 31 outputs and to drive STOHZ0 - 15 to high
- Set the \overline{TRST} pin to low to disable the JTAG TAP controller
- Reset the device by pulsing the \overline{RESET} pin to zero for longer than 1 μ s
- After releasing the \overline{RESET} pin from low to high, wait for a certain period of time (see Note below) for the device to stabilize from the power down state before the first microprocessor port access can occur
- Program CKIN1 - 0 (bit 6 -5) in the Control Register (CR) to define the frequency of the CKi and FPi inputs
- Wait at least 500 μ s prior to the next microport access (see Note below)
- Use the block programming mode to initialize the connection memory
- Release the ODE pin from low to high after the connection memory is programmed

Note: If an external oscillator is used, the waiting time is 500 μ s. Without the external oscillator, if CKi is 16.384 MHz, the waiting time is 500 μ s; if CKi is 8.192 MHz, the waiting time is 1 ms; if CKi is 4.096 MHz, the waiting time is 2 ms.

17.3 Software Reset

In addition to the hardware reset from the \overline{RESET} pin, the device can also be reset by using software reset. There are two software reset bits in the Software Reset Register (SRR). SRSTDPLL (bit 0) is used to reset the DPLL while SRSTSW (bit 1) resets the rest of the switch.

18.0 Pseudo-random Bit Generation and Error Detection

The ZL50022 has one Bit Error Rate (BER) transmitter and one BER receiver for each pair of input and output streams, resulting in 32 transmitters connected to the output streams and 32 receivers associated with the input streams. Each transmitter can generate a BER sequence with a pattern of $2^{15}-1$ pseudo-random code (ITU O.151). Each transmitter can start at any location on the stream and will last for a minimum of 1 channel to a maximum of 1 frame time (125 μ s). The BER receivers and transmitters are enabled by programming the RBEREN (bit 5) and TBEREN (bit 4) in the IMS register. In order to save power, the 32 transmitters and/or receivers can be disabled. (This is the default state.)

Multiple connection memory locations can be programmed for BER tests such that the BER patterns can be transmitted for multiple consecutive output channels. If consecutive input channels are not selected, the BER receiver will not compare the bit patterns correctly. The number of output channels which the BER pattern occupies has to be the same as the number of channels defined in the BER Length Register (BRLR) which defines how many BER channels are to be monitored by the BER receiver.

For each input stream, there is a set of registers for the BER test. The registers are as follows:

- BER Receiver Control Register (**BRCR**) - ST[n]CBER (bit 1) is used to clear the Bit Receiver Error Register (BRER). ST[n]SBER (bit 0) is used to enable the per-stream BER receiver.

- BER Receiver Start Register (**BRSR**) - ST[n]BRS7 - 0 (bit 7 - 0) defines the input channel from which the BER sequence will start to be compared.
- BER Receiver Length Register (**BRLR**) - ST[n]BL8 - 0 (bit 8 - 0) define how many channels the sequence will last. Depending on the data rate being used, the BER test can last for a maximum of 32, 64, 128 or 256 channels at the data rates of 2.048, 4.096, 8.192 or 16.384 Mbps, respectively. The minimum length of the BER test is a single channel. The user must take care to program the correct channel length for the BER test so that the channel length does not exceed the total number of channels available in the stream.
- BER Receiver Error Register (**BRER**) - This read-only register contains the number of counted errors. When the error count reaches 0xFFFF, the BER counter will stop updating so that it will not overflow. ST[n]CBER (bit 1) in the BER Receiver Control Register is used to reset the BRER register.

For normal BER operation, CMM (bit 0) must be 1 in the Connection Memory Low (CM_L). PCC1 - 0 (bits 2 - 1) in the Connection Memory Low must be programmed to "10" to enable the per-stream based BER transmitters. For each stream, the length (or total number of channels) of BER testing can be as long as one whole frame, but the channels MUST be consecutive. Upon completion of programming the connection memory, the corresponding BER receiver can be started by setting ST[n]SBER (bit 0) in the BRER to high. There must be at least 2 frames (250 μ s) between completion of connection memory programming and starting the BER receiver before the BER receiver can correctly identify BER errors. A 16 bit BER counter is used to count the number of bit errors.

19.0 PCM A-law/ μ -law Translation

The ZL50022 provides per-channel code translation to be used to adapt pulse code modulation (PCM) voice or data traffic between networks which use different encoding laws. Code translation is valid in both Connection Mode and Message Mode.

In order to use this feature, the Connection Memory High (CM_H) entry for the output channel must be programmed. V/D (bit 4) defines if the traffic in the channel is voice or data. Setting ICL1 - 0 (bits 3 - 2) programs the input coding law and OCL1 - 0 (bits 1 - 0) programs the output coding law as shown in Table 13.

The different code options are:

Input Coding (ICL1 - 0)	Output Coding (OCL1 - 0)	Voice Coding (\bar{V}/D bit = 0)	Data Coding (\bar{V}/D bit = 1)
00	00	ITU-T G.711 A-law	No code
01	01	ITU-T G.711 μ -law	Alternate Bit Inversion (ABI)
10	10	A-law without Alternate Bit Inversion (ABI)	Inverted Alternate Bit Inversion (ABI)
11	11	μ -law without Magnitude Inversion (MI)	All bits inverted

Table 13 - Input and Output Voice and Data Coding

For voice coding options, the ITU-T G.711 A-law and ITU-T G.711 μ -law are the standard rules for encoding. A-law without Alternate Bit Inversion (ABI) is an alternative code that does not invert the even bits (6, 4, 2, 0). μ -law without Magnitude Inversion (MI) is an alternative code that does not perform inversion of magnitude bits (6, 5, 4, 3, 2, 1, 0).

When transferring data code, the option "no code" does not invert the bits. The Alternate Bit Inversion (ABI) option inverts the even bits (6, 4, 2, 0) while the Inverted Alternate Bit Inversion (ABI) inverts the odd bits (7, 5, 3, 1). When the "All bits inverted" option is selected, all of the bits (7, 6, 5, 4, 3, 2, 1, 0) are inverted.

The input channel and output channel encoding law are configured independently. If the output channel coding is set to be different from the input channel, the ZL50022 performs translation between the two standards. If the input

and output encoding laws are set to the same standard, no translation occurs. As the \bar{V}/D (bit 4) of the Connection Memory High (CM_H) must be set on a per-channel basis, it is not possible to translate between voice and data encoding laws.

20.0 Quadrant Frame Programming

By programming the Stream Input Quadrant Frame Registers (SIQFR0 - 31), users can divide one frame of input data into four quadrant frames and can force the LSB or MSB of every input channel in these quadrants to one or zero for robbed-bit signaling. The four quadrant frames are defined as follows:

Data Rate	Quadrant 0	Quadrant 1	Quadrant 2	Quadrant 3
2.048 Mbps	Channel 0 - 7	Channel 8 - 15	Channel 16 - 23	Channel 24 - 31
4.096 Mbps	Channel 0 - 15	Channel 16 - 31	Channel 32 - 47	Channel 48 - 63
8.192 Mbps	Channel 0 - 31	Channel 32 - 63	Channel 64 - 95	Channel 96 - 127
16.384 Mbps	Channel 0 - 63	Channel 64 - 127	Channel 128 - 191	Channel 192 - 255

Table 14 - Definition of the Four Quadrant Frames

When the quadrant frame control bits, STIN[n]Q3C2 - 0 (bit 11 - 9), STIN[n]Q2C2 - 0 (bit 8 - 6), STIN[n]Q1C2 - 0 (bit 5 - 3) or STIN[n]Q0C2 - 0 (bit 2 - 0), are set, the LSB or MSB of every input channel in the quadrant is forced to "1" or "0" as shown by the following table:

STIN[n]Q[y]C[2:0]	Action
0xx	Normal Operation
100	Replaces LSB of every channel in Quadrant y with '0'
101	Replaces LSB of every channel in Quadrant y with '1'
110	Replaces MSB of every channel in Quadrant y with '0'
111	Replaces MSB of every channel in Quadrant y with '1'
Note: y = 0, 1, 2, 3	

Table 15 - Quadrant Frame Bit Replacement

Note that Quadrant Frame Programming and BER reception cannot be used simultaneously on the same input stream.

21.0 JTAG Port

The JTAG test port is implemented to meet the mandatory requirements of the IEEE-1149.1 (JTAG) standard. The operation of the boundary-scan circuitry is controlled by an external Test Access Port (TAP) Controller.

21.1 Test Access Port (TAP)

The Test Access Port (TAP) accesses the ZL50022 test functions. It consists of three input pins and one output pin as follows:

- **Test Clock Input (TCK)** - TCK provides the clock for the test logic. TCK does not interfere with any on-chip clock and thus remains independent in the functional mode. TCK permits shifting of test data into or out of the Boundary-Scan register cells concurrently with the operation of the device and without interfering with the on-chip logic.

- **Test Mode Selection Inputs (TMS)** - The TAP Controller uses the logic signals received at the TMS input to control test operations. The TMS signals are sampled at the rising edge of the TCK pulse. This pin is internally pulled to high when it is not driven from an external source.
- **Test Data Input (TDi)** - Serial input data applied to this port is fed either into the instruction register or into a test data register, depending on the sequence previously applied to the TMS input. The registers are described in a subsequent section. The received input data is sampled at the rising edge of the TCK pulse. This pin is internally pulled to high when it is not driven from an external source.
- **Test Data Output (TDo)** - Depending on the sequence previously applied to the TMS input, the contents of either the instruction register or test data register are serially shifted out towards TDo. The data from TDo is clocked on the falling edge of the TCK pulses. When no data is shifted through the boundary scan cells, the TDo driver is set to a high impedance state.
- **Test Reset (TRST)** - Resets the JTAG scan structure. This pin is internally pulled to high when it is not driven from an external source.

21.2 Instruction Register

The ZL50022 uses the public instructions defined in the IEEE-1149.1 standard. The JTAG interface contains a four-bit instruction register. Instructions are serially loaded into the instruction register from the TDi when the TAP Controller is in its shifted-OR state. These instructions are subsequently decoded to achieve two basic functions: to select the test data register that may operate while the instruction is current and to define the serial test data register path that is used to shift data between TDi and TDo during data register scanning.

21.3 Test Data Registers

As specified in the IEEE-1149.1 standard, the ZL50022 JTAG interface contains three test data registers:

- **The Boundary-Scan Register** - The Boundary-Scan register consists of a series of boundary-scan cells arranged to form a scan path around the boundary of the ZL50022 core logic.
- **The Bypass Register** - The Bypass register is a single stage shift register that provides a one-bit path from TDi to TDo.
- **The Device Identification Register** - The JTAG device ID for the ZL50022 is 0C36614B_H

23.0 Detailed Register Description

External Read/Write Address: 0000 _H Reset Value: 0000 _H															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	SLV_DPLLEN	OPM1	OPM0	CKi_LP	FPINPOS	CKINP	FPINP	CKIN1	CKIN0	VAREN	MBPE	OSB	MS1	MS0

Bit	Name	Description															
15 - 14	Unused	Reserved. In normal functional mode, these bits MUST be set to zero.															
13	SLV_DPLLEN	DPLL Enable in Slave Mode (Ignored in Master Mode). When this bit is low, DPLL is disabled in Slave mode. When this bit is high and OSC_EN = 1, the DPLL is enabled in Slave mode. When SLV_DPLLEN is set in Slave mode, CKo[3:0] and FPo[3:0] are generated from CKi and FPi. CKo[5:4] and FPo[5] are locked to the selected input reference (one of REF[3:0]). In this mode of operation, the DPLL retains its functionality, including the generation of the REF_FAIL[3:0] output signals. See Table 7, “ZL50022 Operating Modes” on page 38 for more details.															
12 - 11	OPM1 - 0	Operation Mode. These bits are used to set the device in Master/Slave operation. Refer to Table 7, “ZL50022 Operating Modes” on page 38 for more details.															
10	CKi_LP	CKi and FPi Loopback (Ignored in slave mode) When this bit is low, CKi and FPi are used as input pins. When this bit is high, CKi and FPi are internally looped back from CKo2 (16.384 MHz) and FPo2 respectively, and CKi pin and FPi pin should be tied low or high externally; CKIN1 - 0 (bits 6 - 5) of this register should be programmed to be 00. See Table 7, “ZL50022 Operating Modes” on page 38 for more details.															
9	FPINPOS	Input Frame Pulse (FPi) Position When this bit is low, FPi straddles frame boundary (as defined by ST-BUS). When this bit is high, FPi starts from frame boundary (as defined by GCI-Bus)															
8	CKINP	Clock Input (CKi) Polarity When this bit is low, the CKi falling edge aligns with the frame boundary. When this bit is high, the CKi rising edge aligns with the frame boundary.															
7	FPINP	Frame Pulse Input (FPi) Polarity When this bit is low, the input frame pulse FPi has the negative frame pulse format. When this bit is high, the input frame pulse FPi has the positive frame pulse format.

5	RBEREN	PRBS Receiver Enable When this bit is low, all the BER receivers are disabled. To enable any BER receivers, this bit MUST be high.						
4	TBEREN	PRBS Transmitter Enable When this bit is low, all the BER transmitters are disabled. To enable any BER transmitters, this bit MUST be high.						
3 - 1	BPD2 - 0	Block Programming Data These bits refer to the value to be loaded into the connection memory, whenever the memory block programming feature is activated. After the MBPE bit in the Control Register is set to high and the MBPS bit in this register is set to high, the contents of the bits BPD2 - 0 are loaded into bits 2 - 0 of the Connection Memory Low. Bits 15 - 3 of the Connection Memory Low and bits 15 - 0 of Connection Memory High are zeroed.

0	0	0	0	0	0	0	STIO_PD_EN	BDH	BDL	RBER EN	TBER EN	BPD 2	BPD 1	BPD 0	MBPS
Bit	Name	Description													
0	MBPS	Memory Block Programming Start: A zero to one transition of this bit starts the memory block programming function. The MBPS and BPD2 - 0 bits in this register must be defined in the same write operation. Once the MBPE bit in the Control Register is set to high, the device requires two frames to complete the block programming. After the programming function has finished, the MBPS bit returns to low, indicating the operation is completed. When MBPS is high, MBPS or MBPE can be set to low to abort the programming operation. Whenever the microprocessor writes a one to the MBPS bit, the block programming function is started. As long as this bit is high, the user must maintain the same logical value to the other bits in this register to avoid any change in the device setting.

1	1	1	1	1	1	Stream 31	1	1	1	1	1	1	1	1	Ch 255 (Note 5)

Note 1: A13 must be high for access to data and connection memory positions. A13 must be low to access internal registers.

Note 2: Channels 0 to 31 are used when serial stream is at 2.048 Mbps.

Note 3: Channels 0 to 63 are used when serial stream is at 4.096 Mbps.

Note 4: Channels 0 to 127 are used when serial stream is at 8.192 Mbps.

Note 5: Channels 0 to 255 are used when serial stream is at 16.384 Mbps.

Table 52 - Address Map for Memory Locations (A13 = 1)

24.2 Connection Memory Low (CM_L) Bit Assignment

When the CMM bit (bit 0) in the connection memory low is zero, the per-channel transmission is set to the normal channel-switching. The connection memory low bit assignment for the channel transmission mode is shown in Table 53 on page 87.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
UA EN	V/C	SSA 4	SSA 3	SSA 2	SSA 1	SSA 0	SCA 7	SCA 6	SCA 5	SCA 4	SCA 3	SCA 2	SCA 1	SCA 0	CMM =0

Bit	Name	Description
15	UAEN	Conversion between μ-law and A-law Enable When this bit is low, normal switch without μ -law/A-law conversion. Connection memory high will be ignored. When this bit is high, switch with μ -law/A-law conversion, and connection memory high controls the conversion method.
14	V/C	Variable/Constant Delay Control When this bit is low, the output data for this channel will be taken from constant delay memory. When this bit is set to high, the output data for this channel will be taken from variable delay memory. Note that VAREN must be set in Control Register first.
13 - 9	SSA4 - 0	Source Stream Address The binary value of these 5 bits represents the input stream number.
8 - 1	SCA7 - 0	Source Channel Address The binary value of these 8 bits represents the input channel number.
0	CMM = 0	Connection Memory Mode = 0 If this is low, the connection memory is in the normal switching mode. Bit 13 - 1 are the source stream number and channel number.

Note: For proper μ -law/A-law conversion, the CM_H bits should be set before Bit 15 (UAEN bit) is set to high.

Table 53 - Connection Memory Low (CM_L) Bit Assignment when CMM = 0

When CMM is one, the device is programmed to perform one of the special per-channel transmission modes. Bits PCC0 and PCC1 from connection memory are used to select the per-channel tristate, message or BER test mode as shown in Table 54 on page 88.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
UA EN	0	0	0	0	MSG 7	MSG 6	MSG 5	MSG 4	MSG 3	MSG 2	MSG 1	MSG 0	PCC 1	PCC 0	CMM =1

Bit	Name	Description															
15	UAEN	Conversion between μ-law and A-law Enable (Message mode only) When this bit is low, message mode has no μ -law/A-law conversion. Connection memory high will be ignored. When this bit is high, message mode has μ -law/A-law conversion, and connection memory high controls the conversion method.															
14 - 11	Unused	Reserved In normal functional mode, these bits MUST be set to zero.															
10 - 3	MSG7 - 0	Message Data Bits 8-bit data for the message mode. Not used in the per-channel tristate and BER test modes.															
2 - 1	PCC1 - 0	Per-Channel Control Bits These two bits control the corresponding entry's value on the STio stream. <table><tr><td>PC C1</td><td>PC C0</td><td>Channel Output Mode</td></tr><tr><td>0</td><td>0</td><td>Per Channel Tristate</td></tr><tr><td>0</td><td>1</td><td>Message Mode</td></tr><tr><td>1</td><td>0</td><td>BER Test Mode</td></tr><tr><td>1</td><td>1</td><td>Reserved</td></tr></table>	PC C1	PC C0	Channel Output Mode	0	0	Per Channel Tristate	0	1	Message Mode	1	0	BER Test Mode	1	1	Reserved
PC C1	PC C0	Channel Output Mode															
0	0	Per Channel Tristate															
0	1	Message Mode															
1	0	BER Test Mode															
1	1	Reserved															
0	CMM = 1	Connection Memory Mode = 1 If this is high, the connection memory is in the per-channel control mode which is per-channel tristate, per-channel message mode or per-channel BER mode.															

Note: For proper μ -law/A-law conversion, the CM_H bits should be set before Bit 15 (UAEN bit) is set to high.

Table 54 - Connection Memory Low (CM_L) Bit Assignment when CMM = 1

24.3 Connection Memory High (CM_H) Bit Assignment

Connection memory high provides the detailed information required for μ -law and A-law conversion. ICL and OCL bits describe the Input Coding Law and the Output Coding Law, respectively. They are used to select the expected PCM coding laws for the connection, on the TDM inputs, and on the TDM outputs. The \bar{V}/D bit is used to select the class of coding law. If the \bar{V}/D bit is cleared (to select a voice connection), the ICL and OCL bits select between A-law and μ -law specifications related to G.711 voice coding. If the \bar{V}/D bit is set (to select a data connection), the ICL and OCL bits select between various bit inverting protocols. These coding laws are illustrated in the following table. If the ICL is different than the OCL, all data bytes passing through the switch on that particular connection are translated between the indicated laws. If the ICL and the OCL are the same, no coding law translation is performed. The ICL, the OCL bits and \bar{V}/D bit only have an effect on PCM code translations for constant delay connections, variable delay connections and per-channel message mode.

Note 1:

For proper μ -law/A-law conversion, the CM_H bits should be set before Bit 15 of CM_L is set to high.

Note 2:

Refer to G.711 standard for detail information of different laws.

Table 55 - Connection Memory High (CM_H) Bit Assignment

25.0 Applications

This section contains application-specific details for clock and crystal operation and power supply decoupling.

25.1 OSCi Master Clock Requirement

The device requires a 20 MHz master clock source at the OSCi pin when operating in Master mode or in Divided Slave with OSC mode. The clock source may be either an external clock oscillator connected to the OSCi pin, or an external crystal connected between the OSCi and OSCo pins. If an external clock source is present, OSC_EN must be tied high.

Note that using a crystal is only suitable for wider tolerance applications (i.e. ± 100 ppm). For stratum 4E applications a clock oscillator with a tolerance of ± 32 ppm should be used. See Application Note ZLAN-68 for a list of Oscillators and Crystals that can be used with Zarlink PLL's and Digital Switches with embedded PLL's.

25.1.1 External Crystal Oscillator

When an external crystal oscillator is used, a complete oscillator circuit made up of a crystal, resistor and capacitors is shown in Figure 23 on page 90. XC is a buffered version of the 20 MHz input clock connected to the internal circuitry.

Figure 23 - Crystal Oscillator Circuit

The accuracy of a crystal oscillator circuit depends on the crystal tolerance as well as the load capacitance tolerance. Typically, for a 20 MHz crystal specified with a 32 pF load capacitance, each 1 pF change in load capacitance contributes approximately 9 ppm to the frequency deviation. Consequently, capacitor tolerances and stray capacitances have a major effect on the accuracy of the oscillator frequency. The trimmer capacitor shown in Figure 23 on page 90 may be used to compensate for capacitive effects.

The crystal should be a fundamental mode type - not an overtone. The fundamental mode crystal permits a simpler oscillator circuit with no additional filter components and is less likely to generate spurious responses. The crystal accuracy only affects the output clock accuracy in the freerun or the holdover mode. The crystal specification is as follows:

Frequency	20 MHz
Tolerance	As required
Oscillation Mode	Fundamental
Resonance Mode	Parallel

Load Capacitance	20 pF - 32 pF
Maximum Series Resistance	35 Ω
Approximate Drive Level	1 mW

25.1.2 External Clock Oscillator

When an external clock oscillator is used, numerous parameters must be considered. They include absolute frequency, frequency change over temperature, output rise and fall times, output levels and duty cycle.

The output clock should be connected directly (not AC coupled) to the OSCi input of the device, and the OSCo output should be left open as shown in Figure 24 on page 91. XC is a buffered version of the 20 MHz input clock connected to the internal circuitry.

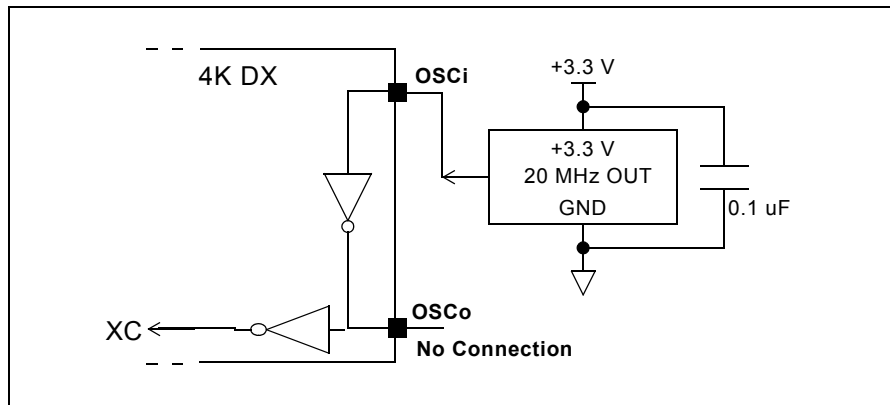

Figure 24 - Clock Oscillator Circuit

For applications requiring ± 32 ppm clock accuracy, the following requirements should be met:

Frequency	20.000 MHz
Tolerance	± 32 ppm
Rise and Fall Time	10 ns
Duty Cycle	40% to 60%

* Note 1: Maximum leakage on pins (output or I/O pins in high impedance state) is over an applied voltage (V_{IN}).

27.0 AC Parameters

AC Electrical Characteristics† - Timing Parameter Measurement Voltage Levels

	Characteristics	Sym.	Level	Units	Conditions
1	CMOS Threshold	V_{CT}	$0.5 V_{DD_IO}$	V	
2	Rise/Fall Threshold Voltage High	V_{HM}	$0.7 V_{DD_IO}$	V	
3	Rise/Fall Threshold Voltage Low	V_{LM}	$0.3 V_{DD_IO}$	V	

† Characteristics are over recommended operating conditions unless otherwise stated.

Figure 25 - Timing Parameter Measurement Voltage Levels

AC Electrical Characteristics[†] - Motorola Non-Multiplexed Bus Mode - Read Access

	Characteristics	Sym	Min.	Typ.	Max.	Units	Test Conditions ²
1	$\overline{\text{CS}}$ de-asserted time	t_{CSD}	15			ns	
2	$\overline{\text{DS}}$ de-asserted time	t_{DSD}	15			ns	
3	$\overline{\text{CS}}$ setup to $\overline{\text{DS}}$ falling	t_{CSS}	0			ns	
4	$\text{R}/\overline{\text{W}}$ setup to $\overline{\text{DS}}$ falling	t_{RWS}	10			ns	
5	Address setup to $\overline{\text{DS}}$ falling	t_{AS}	5			ns	
6	$\overline{\text{CS}}$ hold after $\overline{\text{DS}}$ rising	t_{CSH}	0			ns	
7	$\text{R}/\overline{\text{W}}$ hold after $\overline{\text{DS}}$ rising	t_{RWH}	0			ns	
8	Address hold after $\overline{\text{DS}}$ rising	t_{AH}	0			ns	
9	Data setup to $\overline{\text{DTA}}$ Low	t_{DS}	8			ns	$C_L = 50 \text{ pF}$
10	Data hold after $\overline{\text{DS}}$ rising	t_{DH}	7			ns	$C_L = 50 \text{ pF}$, $R_L = 1 \text{ K}$ (Note 1)
11	Acknowledgement delay time. From $\overline{\text{DS}}$ low to $\overline{\text{DTA}}$ low: Registers Memory	t_{AKD}			75 185	ns ns	$C_L = 50 \text{ pF}$ $C_L = 50 \text{ pF}$
12	Acknowledgement hold time. From $\overline{\text{DS}}$ high to $\overline{\text{DTA}}$ high	t_{AKH}	4		12	ns	$C_L = 50 \text{ pF}$, $R_L = 1 \text{ K}$ (Note 1)
13	$\overline{\text{DTA}}$ drive high to HiZ	t_{AKZ}			8	ns	

Note 1: High impedance is measured by pulling to the appropriate rail with R_L , with timing corrected to cancel time taken to discharge C_L .

Note 2: A delay of 500 μs to 2 ms (see Section 17.2 on page 47) must be applied before the first microprocessor access is performed after the RESET pin is set high.

[†] Characteristics are over recommended operating conditions unless otherwise stated.

9	TRST pulse width	t_{TRSTW}	200			ns	

[†] Characteristics are over recommended operating conditions unless otherwise stated.

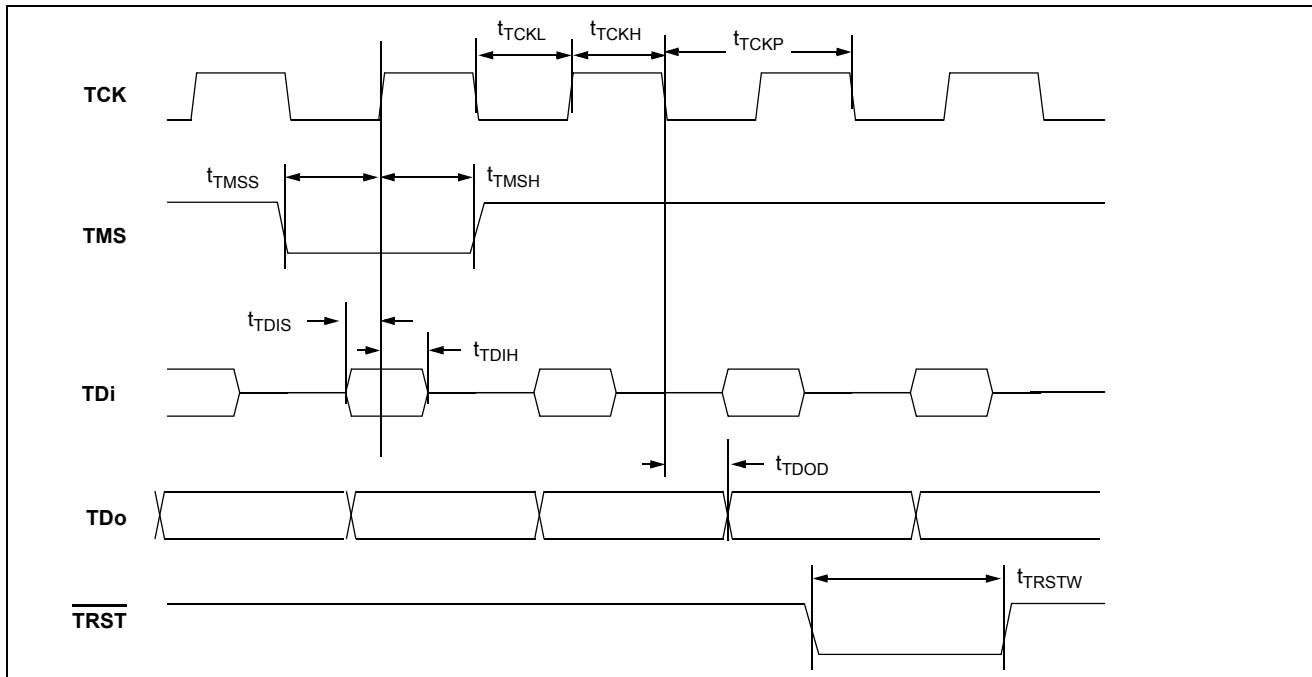

Figure 30 - JTAG Test Port Timing Diagram

AC Electrical Characteristics[†] - OSCi 20 MHz Input Timing

	Characteristic	Sym.	Min.	Typ.	Max.	Units	Notes [‡]
1	Input frequency accuracy		-32 -100		32 100	ppm ppm	Stratum 4E Relaxed Stratum 4E
2	Duty cycle		40		60	%	1
3	Input rise or fall time	t_{IR}, t_{IF}			3	ns	14

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] See "Performance Characteristics Notes" on page 118.

AC Electrical Characteristics[†] - FPi and CKi Timing when CKIN1-0 bits = 00 (16.384 MHz)

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Notes
1	FPi Input Frame Pulse Width	t_{FPIW}	40	61	115	ns	
2	FPi Input Frame Pulse Setup Time	t_{FPIS}	20			ns	
3	FPi Input Frame Pulse Hold Time	t_{FPIH}	20			ns	
4	CKi Input Clock Period	t_{CKIP}	55	61	67	ns	
5	CKi Input Clock High Time	t_{CKIH}	27		34	ns	
6	CKi Input Clock Low Time	t_{CKIL}	27		34	ns	
7	CKi Input Clock Rise/Fall Time	t_{rCKi}, t_{fCKi}			3	ns	
8	CKi Input Clock Cycle to Cycle Variation	t_{CVC}	0		20	ns	

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

AC Electrical Characteristics[†] - FPi and CKi Timing when CKIN1-0 bits = 01 (8.192 MHz)

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Notes
1	FPi Input Frame Pulse Width	t_{FPIW}	90	122	220	ns	
2	FPi Input Frame Pulse Setup Time	t_{FPIS}	45			ns	
3	FPi Input Frame Pulse Hold Time	t_{FPIH}	45			ns	
4	CKi Input Clock Period	t_{CKIP}	110	122	135	ns	
5	CKi Input Clock High Time	t_{CKIH}	55		69	ns	
6	CKi Input Clock Low Time	t_{CKIL}	55		69	ns	
7	CKi Input Clock Rise/Fall Time	t_{rCKi}, t_{fCKi}			3	ns	
8	CKi Input Clock Cycle to Cycle Variation	t_{CVC}	0		20	ns	

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

AC Electrical Characteristics[†] - FPi and CKi Timing when CKIN1-0 bits = 10 (4.096 MHz)

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Notes
1	FPi Input Frame Pulse Width	t_{FPIW}	90	244	420	ns	
2	FPi Input Frame Pulse Setup Time	t_{FPIS}	110			ns	
3	FPi Input Frame Pulse Hold Time	t_{FPIH}	110			ns	
4	CKi Input Clock Period	t_{CKIP}	220	244	270	ns	
5	CKi Input Clock High Time	t_{CKIH}	110		135	ns	
6	CKi Input Clock Low Time	t_{CKIL}	110		135	ns	
7	CKi Input Clock Rise/Fall Time	t_{rCKi}, t_{fCKi}			3	ns	
8	CKi Input Clock Cycle to Cycle Variation	t_{CVC}	0		20	ns	

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

Figure 44 - FPo2 and CKo2 or FPo3 and CKo3 (16.384 MHz) Timing Diagram

AC Electrical Characteristics[†] - FPo2 and CKo2 or FPo3 and CKo3 (16.384 MHz) Timing (Master Mode, Divided Slave Mode, or Multiplied Slave Mode with less than 10 ns of Cycle to Cycle Variation on CKi)

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Notes
1	FPo2 Output Pulse Width	t_{FPW2}	56	61	66	ns	$C_L = 30 \text{ pF}$
2	FPo2 Output Delay from the FPo2 falling edge to the output frame boundary	t_{FODF2}	25		36	ns	
3	FPo2 Output Delay from the output frame boundary to the FPo2 rising edge	t_{FODR2}	25		36	ns	
4	CKo2 Output Clock Period	t_{CKP2}	56	61	66	ns	$C_L = 30 \text{ pF}$
5	CKo2 Output High Time	t_{CKH2}	25		36	ns	
6	CKo2 Output Low Time	t_{CKL2}	25		36	ns	
7	CKo2 Output Rise/Fall Time	t_{rCK2}, t_{fCK2}			5	ns	

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

AC Electrical Characteristics[†] - FPo2 and CKo2 or FPo3 and CKo3 (16.384 MHz) Timing (Multiplied Slave Mode with more than 10 ns of Cycle to Cycle Variation on CKi)

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Notes
1	FPo2 Output Pulse Width	t_{FPW2}	56	61	66	ns	$C_L = 30 \text{ pF}$
2	FPo2 Output Delay from the FPo2 falling edge to the output frame boundary	t_{FODF2}	25		36	ns	
3	FPo2 Output Delay from the output frame boundary to the FPo2 rising edge	t_{FODR2}	25		36	ns	
4	CKo2 Output Clock Period	t_{CKP2}	47	61	76	ns	$C_L = 30 \text{ pF}$
5	CKo2 Output High Time	t_{CKH2}	17		43	ns	
6	CKo2 Output Low Time	t_{CKL2}	17		43	ns	
7	CKo2 Output Rise/Fall Time	t_{rCK2}, t_{fCK2}			5	ns	

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

Figure 45 - FPo3 and CKo3 (32.768 MHz) Timing Diagram

AC Electrical Characteristics[†] - FPo3 and CKo3 (32.768 MHz) Timing (Master Mode, Divided Slave Mode, or Multiplied Slave Mode with less than 10 ns of Cycle to Cycle Variation on CKi)

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Notes
1	FPo3 Output Pulse Width	t_{FPW3}	27	30.5	34	ns	$C_L = 30 \text{ pF}$
2	FPo3 Output Delay from the FPo3 falling edge to the output frame boundary	t_{FODF3}	10		18	ns	
3	FPo3 Output Delay from the output frame boundary to the FPo3 rising edge	t_{FODR3}	12		21	ns	
4	CKo3 Output Clock Period	t_{CKP3}	27	30.5	34	ns	$C_L = 30 \text{ pF}$
5	CKo3 Output High Time	t_{CKH3}	12		19	ns	
6	CKo3 Output Low Time	t_{CKL3}	12		19	ns	
7	CKo3 Output Rise/Fall Time	t_{rCK3}, t_{fCK3}			5	ns	

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

AC Electrical Characteristics[†] - FPo3 and CKo3 (32.768 MHz) Timing (Multiplied Slave Mode with more than 10 ns of Cycle to Cycle Variation on CKi)

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Notes
1	FPo3 Output Pulse Width	t_{FPW3}	27	30.5	34	ns	$C_L = 30 \text{ pF}$
2	FPo3 Output Delay from the FPo3 falling edge to the output frame boundary	t_{FODF3}	12		19	ns	
3	FPo3 Output Delay from the output frame boundary to the FPo3 rising edge	t_{FODR3}	12		19	ns	
4	CKo3 Output Clock Period	t_{CKP3}	17	30.5	44	ns	$C_L = 30 \text{ pF}$
5	CKo3 Output High Time	t_{CKH3}	5		29	ns	
6	CKo3 Output Low Time	t_{CKL3}	12		18	ns	
7	CKo3 Output Rise/Fall Time	t_{rCK3}, t_{fCK3}			5	ns	

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

Figure 46 - FPo4 and CKo4 Timing Diagram (1.544/2.048 MHz)

AC Electrical Characteristics[†] - CKo4 (1.544 MHz) Timing (Only when DPLL is active)

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Notes
1	CKo4 Output Clock Period	t_{CKP4}	645	648	650	ns	$C_L = 30 \text{ pF}$
2	CKo4 Output High Time	t_{CKH4}	320	324	327	ns	
3	CKo4 Output Low Time	t_{CKL4}	320	324	327	ns	
4	CKo4 Output Rise/Fall Time	t_{rCK4}, t_{fCK4}			5	ns	

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

AC Electrical Characteristics[†] - CKo4 (2.048 MHz) Timing (Only when DPLL is active)

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Notes
1	CKo4 Output Clock Period	t_{CKP4}	485	488	492	ns	$C_L = 30 \text{ pF}$
2	CKo4 Output High Time	t_{CKH4}	241	244	247	ns	
3	CKo4 Output Low Time	t_{CKL4}	241	244	247	ns	
4	CKo4 Output Rise/Fall Time	t_{rCK4}, t_{fCK4}			5	ns	

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

Figure 47 - CKo5 Timing Diagram (19.44 MHz)

AC Electrical Characteristics[†] - CKo5 (19.44 MHz) Timing (Only when DPLL is active)

	Characteristic	Sym.	Min.	Typ. [‡]	Max.	Units	Notes
1	FPo5 Output Pulse Width	t_{FPW5}	49	51	55	ns	$C_L = 30 \text{ pF}$
2	FPo5 Output Delay from the FPo5 falling edge to the output frame boundary	t_{FODF5}	22	25	28	ns	
3	FPo5 Output Delay from the output frame boundary to the FPo5 rising edge	t_{FODR5}	21	25	32	ns	
4	CKo5 Output Clock Period	t_{CKP5}	50	51	53	ns	
5	CKo5 Output High Time	t_{CKH5}	23	25	27	ns	
6	CKo5 Output Low Time	t_{CKL5}	24	25	28	ns	
7	CKo5 Output Rise/Fall Time	t_{rCK5}, t_{fCK5}			5	ns	

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] Typical figures are at 25°C and are for design aid only: not guaranteed and not subject to production testing.

AC Electrical Characteristics[†] - REF0-3 Reference Input to CKo Output Timing

	Characteristic	Sym.	Min.	Max.	Units	Notes‡
1	Minimum Input Pulse Width High or Low	t_{RPMIN}	16		ns	1,2,3,14
2	Input Rise or Fall Time	t_{IR} , (or t_{IF})		5	ns	
3	REF input to CKo0 output delay (no input jitter) REF at 8 kHz, 2.048, 4.096, 8.192, 16.384 MHz REF at 1.544 MHz REF at 19.44 MHz	t_{RD}	-7 6 -10	0 15 -2	ns ns ns	

[†] Characteristics are over recommended operating conditions unless otherwise stated.

[‡] See "Performance Characteristics Notes" on page 118.

Figure 48 - REF0 - 3 Reference Input/Output Timing

AC Electrical Characteristics[†] - Master Mode Output Timing

	Characteristic	Sym.	Min.	Max.	Units	Notes‡
1	CKo0 to CKo1 (8.192 MHz) delay	t _{C1D}	-1	2	ns	1-5,14
2	CKo0 to CKo2 (16.384 MHz) delay	t _{C2D}	-1	3	ns	
3	CKo0 to CKo3 (32.768 MHz/16.384 MHz/8.192 MHz/4.096 MHz) delay	t _{C3D}	-4	0	ns	
4	CKo0 to CKo4 (1.544 MHz/2.048 MHz) delay CKo4 at 1.544 MHz CKo4 at 2.048 MHz	t _{C4D}	-12 -2	-7 3	ns ns	
5	CKo0 to CKo5 (19.44 MHz) delay	t _{C5D}	6	12	ns	

† Characteristics are over recommended operating conditions unless otherwise stated.

‡ See "Performance Characteristics Notes" on page 118.

AC Electrical Characteristics[†] - Divided Slave Mode Output Timing

	Characteristic	Sym.	Min.	Max.	Units	Notes‡
1	CKo0 to CKo1 (8.192 MHz) delay	t _{C1D}	-1	2	ns	1-5,14
2	CKo0 to CKo2 (16.384 MHz) delay	t _{C2D}	-1	3	ns	
3	CKo0 to CKo3 (16.384 MHz/8.192 MHz/4.096 MHz) delay	t _{C3D}	-2	2	ns	

† Characteristics are over recommended operating conditions unless otherwise stated.

‡ See "Performance Characteristics Notes" on page 118.

AC Electrical Characteristics[†] - Multiplied Slave Mode Output Timing

	Characteristic	Sym.	Min.	Max.	Units	Notes‡
1	CKo0 to CKo1 (8.192 MHz) delay	t _{C1D}	-1	2	ns	1-5,14
2	CKo0 to CKo2 (16.384 MHz) delay	t _{C2D}	-1	3	ns	
3	CKo0 to CKo3 (32.768 MHz/16.384 MHz/8.192 MHz/4.096 MHz) delay	t _{C3D}	-1	3	ns	

† Characteristics are over recommended operating conditions unless otherwise stated.

‡ See "Performance Characteristics Notes" on page 118.

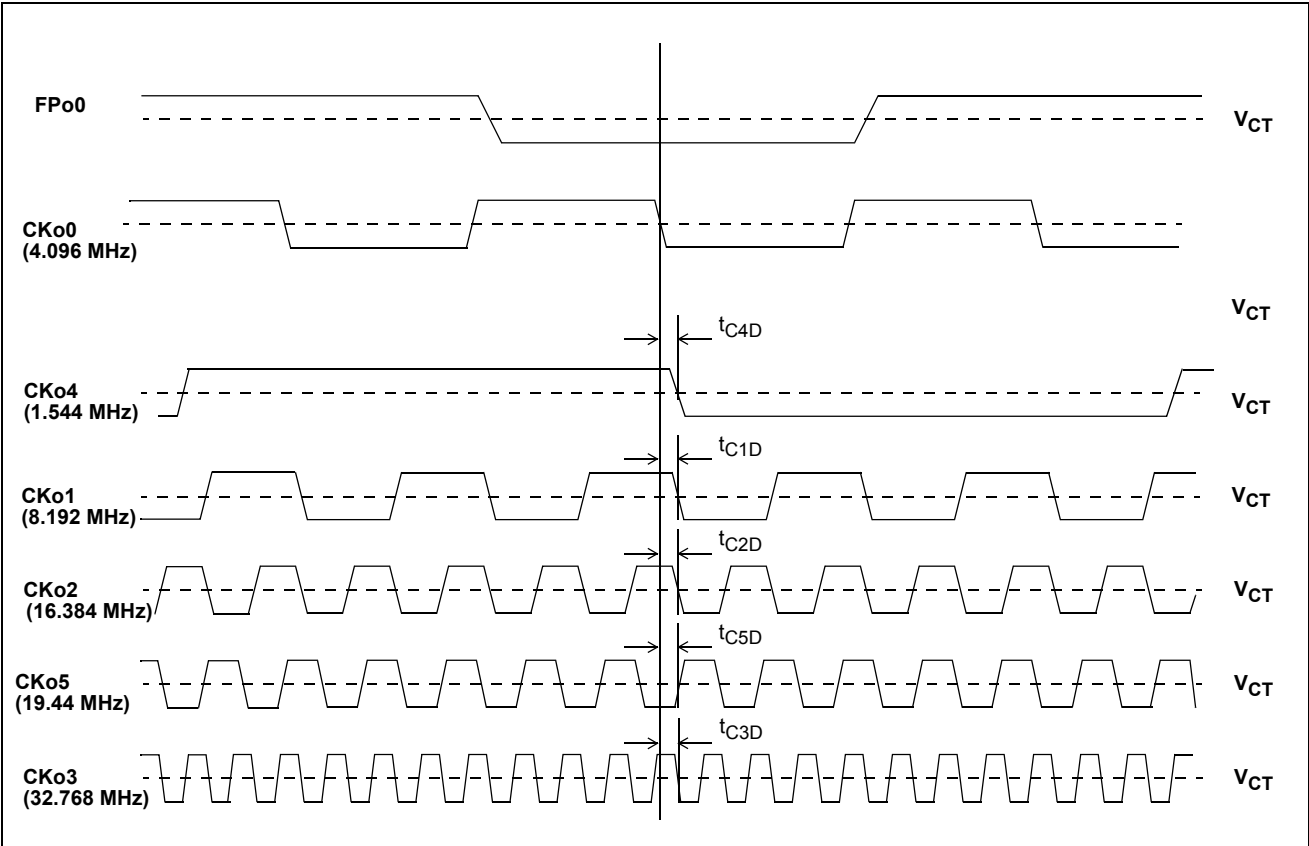

Figure 49 - Output Timing (ST-BUS Format)

DPLL Performance Characteristics† - Accuracy & Switching

	Characteristics	Min	Max	Units	Conditions/ Notes‡
1	Freerun Accuracy	-0.003	0	ppm	1,5,7
2	Initial Holdover Frequency Stability	-0.03	0.03	ppm	1,4,8
3	Pull-in/Hold-in Range (Stratum 4E)	-260	260	ppm	1,3,7,9
4	Reference Far Hysteresis Limit (Stratum 4E)	-82.5	82.5	ppm	1,3,7,9,12
5	Reference Near Hysteresis Limit (Stratum 4E)	-64.5	64.5	ppm	
6	Reference Far Hysteresis Limit (Relaxed Stratum 4E)	-248	248	ppm	1,3,7,9,13
7	Reference Near Hysteresis Limit (Relaxed Stratum 4E)	-242	242	ppm	
8	Output phase continuity for reference switch ¹		31	ns	11
9	Normal output phase alignment speed (phase slope)		56	μs/s	10
10	Normal phase lock time ²		75	s	1,3,7,9,10

1. Reference switching to normal, holdover, or freerun mode

2. -32 to +32 ppm locking

† Characteristics are over recommended operating conditions unless otherwise stated.

‡ See "Performance Characteristics Notes" on page 118.

DPLL Performance Characteristics† - Output Jitter Generation (Unfiltered except for CKo5)

	Characteristics	Typ.‡	Units	Conditions/Notes*
1	Jitter at CKo0 and CKo3 (4.096 MHz)	810	ps-pp	1-6,14
2	Jitter at CKo1 and CKo3 (8.192 MHz)	800	ps-pp	
3	Jitter at CKo2 and CKo3 (16.384 MHz)	710	ps-pp	
4	Jitter at CKo3 (4.096, 8.192, 16.384, or 32.768 MHz)	670	ps-pp	
5	Jitter at CKo4 (1.544 MHz or 2.048 MHz)	1060 630	ps-pp ps-pp	
6	Jitter at CKo5 (19.44 MHz)	770	ps-pp	
	unfiltered jitter	540	ps-pp	
	500 Hz - 1.3 MHz jitter	460	ps-pp	
	65 kHz - 1.3 MHz jitter	510	ps-pp	
	12 kHz - 1.3 MHz jitter			

† Characteristics are over recommended operating conditions unless otherwise stated.

‡ Typical figures are at 25°C and are for design aid only; not guaranteed and not subject to production testing.

* See "Performance Characteristics Notes" on page 118

Performance Characteristics Notes

† Characteristics are over recommended operating conditions unless otherwise stated.

‡ Typical figures are at 25°C, V_{DD_CORE} at 1.8 V and V_{DD_IO} at 3.3 V and are for design aid only: not guaranteed and not subject to production testing.

1. Jitter on master clock input (XIN) is 100 ps pp or less.
2. Jitter on reference input (REF0-3) is 2 ns pp or less.
3. Normal Mode selected.
4. Holdover Mode selected.
5. Freerun Mode selected.
6. Jitter is measured without an output filter.
7. Accuracy of master clock input (XIN) is 0 ppm.
8. Accuracy of master clock input (XIN) is 100 ppm.
9. Capture range is +/-260 ppm; inaccuracy of XIN shifts this range.
10. Phase alignment speed (phase slope) is programmed to 7 ns/125µs.
11. Any input reference switch or state switch (i.e. REF0 to REF3, Normal to Holdover, etc.).
12. Multi-period near limits and far limits are programmed to +/-64.713ppm & +/-82.487ppm respectively. (ST4_LIM = 1)
13. Multi-period near limits and far limits are programmed to +/-240ppm & +/-250ppm respectively. (ST4_LIM = 0)
14. 30 pF load on output pin.

SIDE VIEW

NOTES: —

- Controlling dimensions are in MM.
- Seating plane is defined by the spherical crown of the solder balls.
- Not to scale.
- N is the number of solder balls
- Substrate thickness is 0.36 MM.

NOTE	SQUARE			

Conforms to JEDEC MS-026 BJC Iss. D

Notes:

1. Pin 1 indicator may be a corner chamfer, dot or both, located within a zone of dimension $E1/4 \times D1/4$ from the index corner
2. All dimensioning and tolerancing conform to ANSI Y14.5-1982.
3. Dimensions D1 and E1 do not include mold protrusion - allowable mold protrusion is 0.254 mm on D1 and E1 dimensions.
4. "N" is the total number of terminals
5. Package top dimensions are smaller than bottom dimensions and top of package will not overhang bottom of package
6. Dimension b does not include Dambar protrusion.
7. Controlling Dimensions are in Millimeter
8. A1 is defined as the distance from the seating plane to the lowest point of the package body
