

# HT46R63/HT46C63 A/D with LCD Type 8-Bit MCU

### Features

- Operating voltage: f<sub>SYS</sub>=4MHz: 2.2V~5.5V f<sub>SYS</sub>=8MHz: 3.3V~5.5V
- Operating frequency: External RC or Crystal
- 32.768kHz crystal oscillator used for timing purposes
- Watchdog enable or disable function
- 1x16 bits timer with an overflow interrupt (TMR)
- Time base generator (clock source: 32.768kHz) and RTC interrupts
- 4K×15 program memory
- 208×8 data memory RAM
- Maximum of 32 I/O lines (shared with INT0, INT1, TMR, AN0~AN7, PWM0~PWM3)
- **General Description**

The HT46R63/HT46C63 are 8-bit, high performance, RISC architecture microcontroller devices specifically designed for A/D product applications that interface directly to analog signals and which require LCD Interface. The mask version HT46C63 is fully pin and functionally compatible with the OTP version HT46R63 device.

- 8-level stack
- Up to 0.5 $\mu s$  instruction cycle with 8MHz system clock at V\_DD=5V
- 2 external interrupts (high/low going trigger)
- One comparator
- LCD: 20×3 or 19×4, 1/3 bias with 12 pins logical outputs options. (select by options in unit of 4 pins, ×8 high sink)
- Built-in R type bias generator
- 8 channels 8-bits resolution A/D converter
- 4 channels PWM outputs
- 56-pin SSOP, 100-pin QFP package

The advantages of low power consumption, I/O flexibility, timer functions, oscillator options, multi-channel A/D Converter, Pulse Width Modulation function, HALT and wake-up functions, in addition to a flexible and configurable LCD interface enhance the versatility of these devices to control a wide range of applications requiring analog signal processing and LCD interfacing, such as electronic metering, environmental monitoring, handheld measurement tools, motor driving, etc., for both industrial and home appliance application areas.

### **Block Diagram**

### **Pin Assignment**

### **Pad Assignment**

HT46C63

\* The IC substrate should be connected to VSS in the PCB layout artwork.

### **Pin Description**

Pin Name	I/O	Option	Description
PA0~PA7	I/O	Pull-high Wake-up	I/O lines with pull-high resistors (bit option). I/O modes of each line are con- trolled by related control register bit (PAC). Each line of PA can be optioned as a wake-up input (bit option). I/O configurations: Schmitt trigger/CMOS
PB0/AN0~ PB7/AN7	I/O	Pull-High	I/O lines with pull-high resistors (bit option). I/O modes of each line are con- trolled by related control register bit (PBC). I/O configurations: Schmitt trig- ger/CMOS. Each PB line is pin shared with an A/D converter input.
PC0~PC6, PC7	I/O	Pull-High	I/O lines with pull-high resistors (bit option). I/O modes of each line are con- trolled by related control register bit (PCC). I/O configurations: Schmitt trig- ger/CMOS.
PD0/PWM0~ PD3/PWM3, PD4/INT0, PD5/INT1, PD6/TMR, PD7	I/O	Pull-High PWM Interrupt Falling and/or Rising	I/O lines with pull-high resistors (bit option). I/O modes of each line are con- trolled by related control register bit (PDC). I/O configurations: Schmitt trig- ger/CMOS. The PD0~PD3 can be selected as PWM outputs. INT0/INT1 are falling/rising edge selectable triggers.

Pin Name	I/O	Option	Description
OSC1 OSC2	I O	RC or crystal	A resistor across OSC1 and VDD or a crystal across OSC1 and OSC2 will generate a system clock.
OSC3 OSC4	I O		32768Hz crystal across OSC3 and OSC4 will generate RTC clock signal which only provides system timing.
CMPN	I		Negative input for comparator
CMPP	I	_	Positive input for comparator
СМРО	0		Comparator output
CHGO	0		Comparator output with 32768Hz carrier
VDD	_		Positive power supply
AVDD	_	_	A/D converter Positive power supply, AVDD should be externally connected to VDD
VSS	_		Negative power supply, ground
RES	I		Schmitt trigger reset input
VLCD	I/O		LCD highest voltage; should be connected to VDD with external resistor.
SEG0~SEG18	0	SEG7~SEG18 logical CMOS	LCD segment signal driving outputs SEG7~SEG10 can be optioned as out- put lines. SEG11~SEG14, SEG15~SEG18 can be optioned as a high sink- ing output lines.
COM0~COM2 COM3/SEG19	0	COM3 or SEG19	LCD common signal driving outputs

### **Absolute Maximum Ratings**

Supply VoltageV <sub>SS</sub> –0.3V to V <sub>SS</sub> +6.0V	Storage Temperature50°C to 125°C
Input VoltageV <sub>SS</sub> -0.3V to V <sub>DD</sub> +0.3V	Operating Temperature40°C to 85°C

Note: These are stress ratings only. Stresses exceeding the range specified under "Absolute Maximum Ratings" may cause substantial damage to the device. Functional operation of this device at other conditions beyond those listed in the specification is not implied and prolonged exposure to extreme conditions may affect device reliability.

### **Functional Description**

#### **Execution Flow**

The system clock for the microcontroller is derived from an external RC or crystal oscillator. The system clock is internally divided into four non-overlapping clocks. One instruction cycle consists of 4 system clock cycles.

Instruction fetching and execution are pipelined in such a way that a fetch and decoding takes an instruction cycle while execution take the next instruction cycle. However, the pipelining scheme causes each instruction to effectively execute in a cycle. If an instruction changes the program counter, two cycles are required to complete the instruction.

#### **Program Counter – PC**

The program counter controls the sequence in which the instructions stored in the program memory are executed and its contents specify full range of program memory. After accessing a program memory word to fetch an instruction code, the contents of the program counter are incremented by one. The program counter then points to the memory word containing the next instruction code.

When executing a jump instruction, conditional skip execution, loading PCL (program counter lower-order byte register), subroutine call, initial reset, interrupts or return from subroutine or interrupts, the program counter manipulates the program transfer by loading the address corresponding to each instruction.

The conditional skip is activated by instructions. Once the condition is met, the next instruction, fetched during the current instruction execution, is discarded and a dummy cycle replaces it to get the proper instruction. Otherwise proceed with the next instruction.

The lower-order byte of the program counter (PCL) can be accessed by using software instructions. Moving data into the PCL performs a short jump. The destination will be within the current program ROM page.

Once the control transfer takes place, the execution suffers from having an additional dummy cycle.

#### **Program Memory – PROM**

The program memory is used to store the program instructions which are to be executed. It also contains data, table, and interrupt entries, and is organized into

Mode	Program Counter										
Mode	*11~*8	*7	*6	*5	*4	*3	*2	*1	*0		
Initial Reset	0000	0	0	0	0	0	0	0	0

#### Execution Flow

#### **Program Counter**

Note: \*11~\*0: Program counter bits #11~#0: Instruction code bits S11~S0: Stack register bits @7~@0: PCL bits

4096×15 bits, addressed by the program counter and table pointer.

Certain locations in the program memory are reserved for special usage:

Location 000H

This area is reserved for program initialization. After chip reset, the program always begins execution at location 000H.

Location 004H

This area is reserved for the external interrupt 0 service program. If the  $\overline{\text{INT0}}$  input pin is activated, the interrupt is enabled and the stack is not full, the program begins execution at this location.

Location 008H

This area is reserved for the external interrupt 1 service program. If the  $\overline{INT1}$  input pin is activated, the interrupt is enabled and the stack is not full, the program begins execution at this location.

Location 00CH

This area is reserved for the timer/event counter interrupt service program. If a timer interrupt results from a timer/event counter overflow, and the interrupt is enabled and the stack is not full, the program begins execution at location 00CH.

Location 010H

This area is reserved for the time base interrupt service program. If the a time base time-out occurs, the interrupt is enabled and the stack is not full, the program begins execution at this location.

Location 014H

This area is reserved for the A/D converter interrupt service program. If the interrupt is activated (when the A/D conversion is completed), the interrupt is enabled and the stack is not full, the program begins execution at this location.

Location 018H

This area is reserved for the RTC interrupt service program. When the RTC time-out occurs, the interrupt is enabled and the stack is not full, the program begins execution at this location.

Table location

Any location in the program memory can be used as look-up tables. The instructions "TABRDC [m]" (the current page, 1 page=256 words) and "TABRDL [m]" (the last page) transfer the contents of the lower-order byte to the specified data memory, and the

#### Program Memory

higher-order byte to lower portion of TBLH(08H) and the remaining bits (1 bits) of TBLH are read as "0". The table pointer (TBLP) is read/write register (07H), which indicates the table location. Before accessing the table, the location has to be placed in TBLP. The TBLH is read only and cannot be restored. If the main routine and the ISR(interrupt service routine) both employ the table read instruction, the contents of TBLH in the main routine are likely to be changed by the table read instruction used in the ISR. Errors are thus brought about. Given this, using the table read instruction in the main routine and the ISR simultaneously should be avoided. However, if the table read instruction has to be applied in both main routine and the ISR, the interrupt is supposed to be disabled prior to the table read instruction. It will not be enabled until the TBLH in the main routine has been backup. All table related instructions require two cycles to complete the operation. These areas may function as normal program memory depending upon the requirements.

#### Stack Register – STACK

This is a special part of memory, which is used to save the contents of the program counter only. The stack is organized into 8 levels and is neither part of the data not programmable space, and is not accessible. The activated level is indexed by the stack pointer and is not ac-

Instruction	Table Location											
Instruction	*11	*10	*9	*8	*7	*6	*5	*4	*3	*2	*1	*0
TABRDC [m]	P11	P10	P9	P8	@7	@6	@5	@4	@3	@2	@1	@0
TABRDL [m]	1	1	1	1	@7	@6	@5	@4	@3	@2	@1	@0

#### **Table Location**

P11~P8: Current program counter bits

Note: \*11~\*0: Table location bits @7~@0: Table pointer bits

cessible. At a subroutine call or interrupt acknowledgment, the contents of the program counter are pushed onto the stack. At the end of a subroutine or an interrupt routine, signaled by a return instruction (RET or RETI), the program counter is restored to its previous value from the stack. After a chip reset, the stack pointer will point to the top of the stack.

If the stack is full and a non-masked interrupt takes place, the interrupt request flag will be recorded but the acknowledgment will be inhibited. When the stack pointer is decreased (by RET or RETI), the interrupt will be serviced. This feature prevents stack overflow allowing the programmer to use the structure more easily. In similar case, if the stack is full and a "call" is subsequently executed, stack overflow occurs and the first entry will be lost (only the most recent 8 return addresses are stored).

#### Data Memory – RAM

The data memory is designed with  $239 \times 8$  bits. The data memory is divided into two functional groups: special function registers and general purpose data memory ( $208 \times 8$ ). Most are read/write, but some are read only.

The special function registers include the indirect addressing register 0 and 1 (R0;00H, R1;02H), memory pointer 0 and 1 (MP0;01H, MP1;03H), bank pointer (BP:04H), accumulator (ACC;05H), program counter lower-order byte register (PCL;06H), table pointer (TBLP;07H), table higher-order byte register (TBLH;08H), real time clock control register (RTCC;09H), status register (STATUS;0AH), interrupt control register (INTC0;0BH), timer higher-order byte register (TMRH;0CH), timer lower-order byte register (TMRL;0DH), timer control register (TMRC;0EH), I/O port data registers (PA;12H, PB;14H, PC;16H, PD;18H), I/O port control registers (PAC;13H, PBC;15H, PCC;17H, PDC;19H), PWM0 (1AH), PWM1 (1BH), PWM2 (1CH), PWM3 (1DH), INTC1 (1EH), the A/D result register (ADR;21H), the A/D control register (ADCR;22H) and the A/D clock setting register (ACSR;23H). The remaining space before the 30H is reserved for future expansion and reading these locations will return the result "00H". The general-purpose data memory, addressed from 30H to FFH, is used for data and control information under instruction commands.

All of the data memory areas can handle arithmetic, logic, increment, decrement and rotate operations directly. Except for some dedicated bits, each bit in the data memory can be set and cleared by "SET [m].i" and "CLR [m].i", respectively. They are also indirectly accessible through memory pointers (MP0 and MP1).

00H Indirect Addressing Register 0 MP0 01H 02H Indirect Addressing Register 1 MP1 03H ΒP 04H 05H ACC 06H PCI 07H TBLP 08H TBLH 09H RTCC 0AH STATUS 0BH INTC0 0CH TMRH 0DH TMRL 0FH TMRC 0FH 10H 11H 12H PA Special Purpose 13H PAC DATA MEMORY 14H PB 15H PBC 16H PC 17H PCC 18H PD 19H PDC 1AH PWM0 1BH PWM1 1CH PWM2 1DH PWM3 1EH INTC1 1FH 20H 21H ADR 22H ADCR 23H ACSR 24H 2FH 30H General Purpose : Unused Data Memory Read as "00" (208 Bytes) FFH

#### RAM Mapping

#### Indirect Addressing Register

Location 00H (02H) is indirect addressing registers that are not physically implemented. Any read/write operation of [00H] ([02H]) will access data memory pointed to by MP0 (MP1). Reading location 00H (02H) itself indirectly will return the result "00H". Writing indirectly results in no operation.

The memory pointers are 8-bit registers. Only the MP1/R1 can be used to access the LCD RAM (BP=1).

Labels	Bits	Function
с	0	C is set if an operation results in a carry during an addition operation or if a borrow does not take place during a subtraction operation; otherwise C is cleared. C is also affected by a rotate through carry instruction.
AC	1	AC is set if an operation results in a carry out of the low nibbles in addition or no borrow from the high nibble into the low nibble in subtraction; otherwise AC is cleared.
Z	2	Z is set if the result of an arithmetic or logical operation is zero; otherwise Z is cleared.
ov	3	OV is set if the operation results in a carry into the highest-order bit but not a carry out of the high- est-order bit, or vice versa; otherwise OV is cleared.
PDF	4	PDF is cleared by a system power-up or executing the "CLR WDT" instruction. PDF is set by exe- cuting the "HALT" instruction.
то	5	TO is cleared by system power-up or executing the "CLR WDT" or "HALT" instruction. TO is set by a WDT time-out.
	6, 7	Unused bit, read as "0"

#### **Status Register**

#### **Bank Pointer**

The bank pointer is used to assign the accessed RAM bank. When the users want to access the RAM bank "0" a 0 should be loaded onto BP. When the BP is equal to "1", the LCD RAM will be accessed (use MP1/R1 indirect addressing only). RAM locations before 40H in any bank are overlapped.

#### Accumulator

The accumulator is closely related to ALU operations. It is also mapped to location 05H of the data memory and can carry out immediate data operations. The data movement between two data memory locations must pass through the accumulator.

#### Arithmetic and Logic Unit – ALU

This circuit performs 8-bit arithmetic and logic operations. The ALU provides the following functions:

- Arithmetic operations (ADD, ADC, SUB, SBC, DAA)
- Logic operations (AND, OR, XOR, CPL)
- Rotation (RL, RR, RLC, RRC)
- Increment and Decrement (INC, DEC)
- Branch decision (SZ, SNZ, SIZ, SDZ ....)

The ALU not only saves the results of a data operation but also changes the status register.

#### Status Register – STATUS

This 8-bit register (0AH) contains the zero flag (Z), carry flag (C), auxiliary carry flag (AC), overflow flag (OV), power down flag (PDF), and watchdog time-out flag (TO). It also records the status information and controls the operation sequence.

With the exception of the TO and PDF flags, bits in the status register can be altered by instructions like most other registers. Any data written into the status register will not change the TO or PDF flag. In addition operations related to the status register may give different results from those intended. The TO flag can be affected only by system power-up, a WDT time-out or executing the "CLR WDT" or "HALT" instruction. The PDF flag can be affected only by executing the "HALT" or "CLR WDT" instruction or a system power-up.

The Z, OV, AC and C flags generally reflect the status of the latest operations.

In addition, on entering the interrupt sequence or executing the subroutine call, the status register will not be pushed onto the stack automatically. If the contents of the status are important and if the subroutine can corrupt the status register, precautions must be taken to save it properly.

#### Interrupt

The microcontroller provides two external interrupts, an internal timer/event counter overflow interrupt, a time base time-out interrupt, an A/D converter end-of-conversion interrupt and a real time clock time-out interrupt. The interrupt control registers (INTC0: 0BH and INTC1: 1EH) contains the interrupt control bits to set the enable or disable and the interrupt request flags.

Once an interrupt subroutine is serviced, all the other interrupts will be blocked (by clearing EMI bit). This scheme may prevent any further interrupt nesting. Other interrupt requests may happen during this interval but only the interrupt request flags are recorded. If a certain interrupt requires servicing within the service routine, the programmer may set the EMI and the corresponding bit of INTC0/INTC1 to allow interrupt nesting. If the stack is full, the interrupt request will not be acknowledged, even if the related interrupt is enabled, until the SP is decreased. If immediate service is desired, the stack has to be prevented from becoming full.

All these kinds of interrupts have the wake-up capability. As an interrupt is serviced, a control transfer occurs by pushing the program counter onto the stack and then branching to subroutines at specified location(s) in the program memory. Only the program counter is pushed onto the stack. If the contents of the register or status register are altered by the interrupt service program, which corrupts the desired control sequence, the programmer should save these contents first.

External interrupts are triggered by a high to low and/or low to high transition of INTO/INT1 and the related interrupt request flag (bit 4/5 of INTC0 ) will be set. When the interrupt is enabled, the stack is not full and the external interrupt is active, a subroutine call to location 004H/008H will occur. The external interrupt request flag and EMI bits will cleared to disable other interrupts.

The internal timer/event counter interrupt is initialized by setting the timer/event counter interrupt request flag (bit 6 of INTC0), caused by a timer overflow. When the interrupt is enabled, the stack is not full and the timer/event counter interrupt request flag is set, a subroutine call to location 00CH will occur. The related interrupt request flag will be reset and the EMI bit cleared to disable further interrupts.

The time base time-out interrupt is initialized by setting the time base time-out interrupt request flag (bit 4 of INTC1), caused by a time base time-out. When the interrupt is enabled, the stack is not full and the time base time-out interrupt request flag is set, a subroutine call to location 010H will occur. The related interrupt request flag will be reset and the EMI bit cleared to disable further interrupts.

The A/D converter end-of-conversion interrupt is initialized by setting the A/D end-of-conversion interrupt request flag (bit 5 of INTC1), caused by an end of A/D conversion. When the interrupt is enabled, the stack is not full and the end of A/D conversion interrupt request flag is set, a subroutine call to location 014H will occur. The related interrupt request flag will be reset and the EMI bit cleared to disable further interrupts.

The real time clock time-out interrupt is initialized by setting the real time clock interrupt request flag (bit 6 of INTC1), caused by a RTC time-out. When the interrupt is enabled, the stack is not full and the RTC time-out interrupt request flag is set, a subroutine call to location 018H will occur. The related interrupt request flag will be reset and the EMI bit cleared to disable further interrupts.

During the execution of an interrupt subroutine, other interrupt acknowledgments are held until the RETI instruction is executed or the EMI bit and the related interrupt control bit are set to "1" (of course, if the stack is not full). To return from the interrupt subroutine, "RET" or "RETI" may be invoked. RETI will set the EMI bit to enable an interrupt service, but RET will not. Interrupts, occurring in the interval between rising edge of two consecutive T2 pulses, will be serviced on the later of the two T2 pulses, if the corresponding interrupts are enabled. In the case of simultaneous requests the priorities in the follow table apply. These can be masked by clearing the EMI bit.

Interrupt Source	Priority	Vector
External Interrupt 0	1	004H
External Interrupt 1	2	008H
Timer/Event Counter Overflow Interrupt	3	00CH
Time Base Time-out Interrupt	4	010H
End of A/D Conversion Interrupt	5	014H
RTC Time-out Interrupt	6	018H

The external interrupt 0/1 request flags (EI0F/EI1F), timer/event counter interrupt request flag (TF), time base interrupt request flag (TBF), A/D converter interrupt request flag (ADF), RTC interrupt request flag (RTF), enable external interrupt 0/1 (EE0I/EE1I), enable timer/event counter interrupt bit (ETI), enable time base interrupt (ETBI), enable A/D converter interrupt (EADI), enable RTC interrupt (ERTI) and enable master interrupt bit(EMI) constitute interrupt control registers (INTC0/INTC1) which is located at 0BH/1EH in the data memory. EMI, EE0I, EE1I, ETI, EADI and ERTI are used to control the enabling/disabling of interrupts. These bits prevent the requested interrupts from being serviced. Once the interrupt request flags (EI0F, EI1F, TF, TBF, ADF, RTF) are set, they will remain in the INTC0/INTC1 until the interrupts are serviced or cleared by software instructions.

It is suggested that a program does not use the "call" within a interrupt subroutine. It because interrupts often occur in an unpredictable manner or need to be serviced immediately in some applications. If only one stack is left and enabling the interrupt is not well controlled, the original control sequence will be damaged once the "CALL" operates in the interrupt subroutine. The definitions of INTC0 and INTC1 registers are as shown.

Bit No.	Label	Function						
INTC0	INTC0 Register							
0	EMI	Controls the master (global) interrupt (1= enabled; 0= disabled)						
1	EEI0	Controls the external interrupt 0 (1= enabled; 0= disabled)						
2	EEI1	Controls the external interrupt 1 (1= enabled; 0= disabled)						
3	ETI	Controls the timer/event counter over- flow interrupt (1= enabled; 0= disabled)						
4	EIF0	External interrupt 0 request flag (1= active; 0= inactive)						

Bit No.	Label	Function
5	EIF1	External interrupt 1 request flag (1= active; 0= inactive)
6	TF	Timer/Event Counter overflow request flag (1= active; 0= inactive)
7	_	Unused bit, read as "0"
INTC1	Regist	er
0	ETBI	Controls the time base interrupt (1= enabled; 0= disabled)
1	EADI	Controls the A/D converter interrupt (1= enabled; 0= disabled)
2	ERTI	Controls the real time clock interrupt (1= enabled; 0= disabled)
3	_	Unused bit, read as "0"
4	TBF	Time base time-out interrupt 0 request flag (1= active; 0= inactive)
5	ADF	End of A/D conversion interrupt request flag (1= active; 0= inactive)
6	RTF	RTC time-out interrupt request flag (1= active; 0= inactive)
7	_	Unused bit, read as "0"

#### **Oscillator Configuration**

There are four oscillator circuits implemented in the micro-controller.

Two of them are designed for system clocks, namely the external RC oscillator and the crystal oscillator, which

are determined by options. The HALT mode stops the system oscillator and resists the external signal to conserve power. Another one is a 32768Hz crystal oscillator, which only provides use for real time clock. The other one is a built-in 12KHz RC oscillator, which is used for WDTOSC.

If the system clock uses the external RC oscillator, an external resistor between OSC1 and VDD is required and the resistance should range from  $24k\Omega$  to  $1M\Omega$ . The system clock, divided by 4, is available on OSC2, which can be used to synchronize external logic.

If the system clock uses the crystal oscillator, a crystal across OSC1 and OSC2 is needed to provide the feedback and phase shift required for the oscillator, and no other external components are demanded. Instead of a crystal, the resonator can also be connected between OSC1 and OSC2 to get a frequency reference, but two external capacitors in OSC1 and OSC2 are required.

If the RTCOSC is used, a crystal across OSC3 and OSC4 is needed to provide the feedback and phase shift required for the oscillator, and no other external components are demanded.

#### Watchdog Timer – WDT

The clock source of WDT (and LCD, RTC, Time Base ) is implemented by a dedicated crystal oscillator (32.768kHz: RTCOSC) or instruction clock (system frequency divided by 4:  $f_{SYS}/4$ ) or a dedicated RC oscillator (12KHz:WDTOSC) decided by options. This timer is designed to prevent a software malfunction or sequence from jumping to an unknown location with unpredictable

Watchdog Timer

results. The watchdog timer can be disabled by options. If the watchdog timer is disabled, all the executions related to the WDT result in no operation. The WDT time-out period is fixed as 2<sup>16</sup>/f<sub>S</sub>. The f<sub>S</sub> means the clock frequency of WDT, time base, RTC and LCD. If WDTOSC is selected as the WDT clock, the time-out period may vary with temperatures, VDD and process variations. The WDTOSC and RTCOSC can be still running (decided by option) at the halt mode if they are selected as the WDT clock source. Once the 32.768kHz oscillator (with a period of 31.25µs normally) is selected to be the clock source of WDT (and LCD, RTC, Time Base), it is directly divided by 2<sup>16</sup> to get the nominal time-out period of 2 seconds. If the WDT clock comes from the instruction clock, the WDT will stop counting and lose its protecting purpose in halt mode. In this situation the logic can only be restarted by external logic. If the device operates in a noisy environment, using the RTCOSC or WDTOSC is strongly recommended, since the HALT will stop the system clock.

The overflow of WDT under normal operation will initialize "chip reset" and set the status bit "TO". But in the HALT mode, the overflow will initialize a "warm reset", and only the PC and SP are reset to zero. To clear the contents of WDT, 3 methods are adopted; external reset (a low level to RES), software instruction(s) and a HALT instruction. The software instruction(s) include "CLR WDT" and the other set - "CLR WDT1" and "CLR WDT2" Of these two types of instruction, only one can be active depending on the options - "CLR WDT times selection option". If the "CLR WDT" is selected (i.e. CLRWDT times equal one), any execution of the "CLR WDT" instruction will clear the WDT. In the case that "CLR WDT1" and "CLR WDT2" are chosen (i.e. CLR WDT times equal two), these two instructions must be executed to clear the WDT; otherwise, the WDT may reset the chip as a result of time-out. The RTC oscillator should be designed as an auto-speed-up oscillator. After the RTC oscillator is oscillating, the auto-speed-up should be turned off.

#### **Time Base Generator**

There is a time base generator implemented in the micro-controller. The time base generator provides time-out periods selection whose range from  $f_S/2^{12}$  to  $f_S/2^{15}$ . When the time base time-out occurs and the stack is not full and the time base interrupt is enabled, an interrupt subroutine call to ROM location 010H will activate.

#### **RTC Generator**

There is an RTC generator implemented in the micro-controller. The RTC generator provides software configurable real time clock periods whose range from  $f_S/2^8$  to  $f_S/2^{15}$ . When the RTC time-out occurs and the stack is not full and the RTC interrupt is enabled, an in-

terrupt subroutine call to ROM location 018H will activate. The RTCC is the real time clock control register used to select the division ratio of RTC clock sources. RTCC.7~RTCC.3 cannot be used.

RTCC.2	RTCC.1	RTCC.0	RTC clock divided factor
0	0	0	2 <sup>8</sup>
0	0	1	2 <sup>9</sup>
0	1	0	2 <sup>10</sup>
0	1	1	2 <sup>11</sup>
1	0	0	2 <sup>12</sup>
1	0	1	2 <sup>13</sup>
1	1	0	2 <sup>14</sup>
1	1	1	2 <sup>15</sup>

#### **Power Down Operation – HALT**

The HALT mode is initialized by the "HALT" instruction and results in the following...

- The system oscillator will be turned off but the WDTOSC or RTCOSC will stop or keep running decided by option (If the WDTOSC or RTCOSC is selected)
- The contents of the on-chip RAM and registers remain unchanged.
- WDT will be cleared and recounted again (if the WDT clock is from the WDTOSC or RTCOSC).
- All of the I/O ports maintain their original status.
- The PDF flag is set and the TO flag is cleared.

The system can leave the HALT mode by means of an external reset, an interrupt, an external falling edge signal on port A or a WDT overflow. An external reset causes a device initialization and the WDT overflow performs a "warm reset". After the TO and PDF flags are examined, the reason for chip reset can be determined. The PDF flag is cleared by system power-up or executing the "CLR WDT" instruction and is set when executing the "HALT" instruction. The TO flag is set if the WDT time-out occurs, and causes a wake-up that only resets the PC and SP; the others keep their original status.

The port A wake-up and interrupt methods can be considered as a continuation of normal execution. Each bit in port A can be independently selected to wake up the device by the option. Awakening from an I/O port stimulus, the program will resume execution of the next instruction. If it is awakening from an interrupt, two sequences may happen. If the related interrupt is disabled or the interrupt is enabled but the stack is full, the program will resume execution at the next instruction. If the interrupt is enabled and the stack is not full, the regular interrupt response takes place. If an interrupt request flag is set to "1" before entering the HALT mode, the wake-up function of the related interrupt will be disabled.

Once a wake-up event occurs, it takes 1024  $t_{SYS}$  (system clock period) to resume normal operation. In other words, a dummy period will be inserted after wake-up. If the wake-up results from an interrupt acknowledgment, the actual interrupt subroutine execution will be delayed by one or more cycles. If the wake-up results in the next instruction execution, this will be executed immediately after the dummy period is finished.

To minimize power consumption, all the I/O pins should be carefully managed before entering the HALT status.

The 32.768kHz crystal oscillator still run or stop in the halt mode. (decided by option)

#### Reset

There are three ways in which a reset can occur:

- RES reset during normal operation
- RES reset during HALT
- WDT time-out reset during normal operation

The WDT time-out during HALT is different from other chip reset conditions, since it can perform a "warm reset" that resets only the PC and SP, leaving the other circuits in their original state. Some registers remain unchanged during other reset conditions. Most registers are reset to the "initial condition" when the reset conditions are met. By examining the PDF and TO flags, the program can distinguish between different "chip resets".

то	PDF	Reset Conditions
0	0	RES reset during power-up
u	u	RES reset during normal operation
0	1	RES wake-up HALT
1	u	WDT time-out during normal operation
1	1	WDT wake-up HALT

Note: "u" means unchanged

To guarantee that the system oscillator is started and stabilized, the SST (system start-up timer) provides an extra-delay to delay 1024 system clock pulses when system power-up or the system awakes from the HALT state.

When the system power-up occurs, the SST delay is added during the reset period. But when the reset comes from the RES pin, the SST delay is disabled. Any wake-up from HALT will enable the SST delay.

An extra option load time delay is added during system reset (power-up, WDT time-out at normal mode or  $\overrightarrow{\mathsf{RES}}$  reset).

The chip reset statuses of the functional units are as shown.

PC	000H
Interrupt	Disable
WDT	Clear. After master reset, WDT begins counting
Timer/Event Counter	Off
Input/Output Ports	Input mode
SP	Points to the top of the stack

#### **Timer/Event Counter**

A timer/event counter is implemented in the device. The timer/event counter contains a 16-bit programmable count-up counter and the clock may come from an external source or the internal clock source.

The internal clock source is the system clock divided by 4:  $f_{SYS}/4$ . The external clock input allows the user to count external events, measure time intervals or pulse widths, or to generate an accurate time base.

There are 3 registers related to timer/event counter; TMRH(0CH), TMRL(0DH), TMRC(0EH). Writing TMRL only stores the data into a low byte buffer, and writing TMRH will put the written data and the low contents of low byte buffer to preload register (16 bits) simultaneously. The timer/event counter preload register is changed by writing TMRH operations and writing TMRL will keep the timer/event counter preload register unchanged.

Reading TMRH will also latch the TMRL into the low byte buffer to avoid the false timing problem. Reading TMRL returns the contents of the low byte buffer. In other words, the low byte of timer/event counter cannot be read directly. It has to read the TMRH first to make the low byte contents of timer/event counter latched into the buffer. The TMRC is the timer/event counter control register, which defines the operating mode, counting enable or disable and active edge.

The TM0, TM1 bits define the operating mode. The event count mode is used to count external events, which means the clock source comes from an external (TMR) pin. The timer mode functions as a normal timer with the clock source coming from  $f_{SYS}/4$ . The pulse width measurement mode can be used to count the high or low level duration of the external signal (TMR). The counting is based on  $f_{SYS}/4$ .

In the event count or timer mode, once the timer/event counter starts counting, it will count from the current contents in the timer/event counter to FFFFH. Once overflow occurs, the counter is reloaded from the timer/event counter preload register and generates the corresponding interrupt request flag (TF; bit 6 of INTC0) at the same time.

In pulse width measurement mode with the TON and TE bits are equal to one, once the TMR has received a transition from low to high (or high to low if the TE bit is 0) it will start counting until the TMR returns to the original level and reset the TON. The measured result will remain in the timer/event counter even if the activated transition occurs again. In other words, only one cycle measurement can be done. Until setting the TON, the cycle measurement will function again as long as it receives further transition pulse. Note that, in this operating mode, the timer/event counter starts counting not according to the logic level but according to the transition edges. In the case of counter overflows, the counter is reloaded from the timer/event counter preload register and issues the interrupt request just like the other two modes.

To enable the counting operation, the timer ON bit (TON; bit 4 of TMRC) should be set to 1. In the pulse width measurement mode, the TON will be cleared automatically after the measurement cycle is complete. But in the other two modes the TON can only be reset by instructions. The overflow of the timer/event counter is one of the wake-up sources. No matter what the operation mode is, writing a 0 to ETI can disabled the corresponding interrupt service.

In the case of timer/event counter OFF condition, writing data to the timer/event counter preload register will also load the data to timer/event counter. But if the timer/event counter is turned on, data written to the timer/event counter will only be kept in the timer/event counter preload register. The timer/event counter will still operate until the overflow occurs (a timer/event counter reloading will occur at the same time).

**Timer/Event Counter** 

When the timer/event counter (reading TMRH) is read, the clock will be blocked to avoid errors. As this may results in a counting error, this must be taken into consideration by the programmer.

Label (TMRC)	Bits	Function
_	0~2	Unused bits, read as "0"
TE	3	To define the active edge of TMR pin in- put signal (0=active on low to high; 1=active on high to low)
TON 4		To enable or disable timer counting (0=disabled; 1=enabled)
_	5	Unused bit, read as "0"
TM0 TM1	6 7	To define the operating mode 01=Event count mode (external clock) 10=Timer mode (internal clock) 11=Pulse width measurement mode 00=Unused

### TMRC Register

#### Input/Output Ports

There are 32 bi-directional input/output lines in the micro-controller, labeled from PA to PD, which are mapped to the data memory of [12H], [14H], [16H] and [18H], respectively. All of these I/O ports can be used as input and output operations. For input operation, these ports are non-latching, that is, the inputs must be ready at the T2 rising edge of instruction "MOV A,[m]" (m=12H, 14H, 16H or 18H). For output operation, all the data is latched and remains unchanged until the output latch is rewritten.

Each I/O line has its own control register (PAC, PBC, PCC, PDC) to control the input/output configuration. With this control register, CMOS output or schmitt trigger input with or without (depends on options) pull-high resistor structures can be reconfigured dynamically (i.e., on-the fly) under software control. To function as an input, the corresponding latch of the control register has to be set as "1". The pull-high resistor (if the pull-high resistor is enabled) will be exhibited automatically. The input sources are also dependent on the control register. If the control register bit is "1", the input will read the pad state ("mov" and read-modify-write instructions). If the control register bit is "0", the contents of the latches will move to internal data bus ("mov" and read-modify-write instructions). The input paths (pad state or latches) of read-modify-write instructions are dependent on the control register bits. For output function, CMOS is the only configuration. These control registers are mapped to locations 13H, 15H, 17H and 19H.

After a chip reset, these input/output lines stay at a high level (pull-high options) or floating state (non-pull-high options). Each bit of these input/output latches can be set or cleared by "SET [m].i" (m=12H, 14H, 16H or 18H) instructions. Some instructions first input data and then follow the output operations. For example, "SET [m].i" CLR [m].i", "CPLA [m]" read the entire port states into the CPU, execute the defined operations (bit-operation),

and then write the results back to the latches or the accumulator.

Each line of port A has the capability of waking-up the device. The pull-high resistor of each I/O line is decided by options.

#### Comparator

There is a comparator implemented in this microcontroller. This comparator can be enabled/disabled by options. Its inputs are CMPP(+) and CMPN(-) and outputs are CMPO and CHGO. When the CMPN input level is less than the level of CMPP, the CMPO output is  $V_{DD}$ . When the CMPN input level is higher than the level of CMPP, the CMPO output is  $V_{SS}$ .

The CHGO signal is combined with CMPO and 32768Hz carrier if 32768Hz RTC oscillator is applied.

This comparator also can be disabled by options. When the system enters halt mode, the comparator is disabled to reduce power consumption. Once the comparator is disabled, the CHGO and CMPO will stay at VSS level.

#### LCD Display Memory

The micro-controller provides an area of embedded data memory for LCD driver. This area is located from 40H to 53H of he RAM Bank 1. Bank pointer (BP; located at 04H of the RAM) is the switch between the general purpose RAM and the LCD display memory. When the BP is set to "1", any data written into 40H~53H (indirect accessing by using the MP1and R1) will effect the LCD display. When the BP is cleared to "0", any data

written into 40H to 53H will access the general purpose data memory. The LCD display memory can be read and written to only by indirect addressing mode using MP1. When data is written into the display data area it is automatically read by the LCD driver which then generates the corresponding LCD driving signals. To turn the display on or off, an "1" or a "0" is written to the corresponding bit of the display memory, respectively. The figure illustrates the mapping between the display memory and LCD pattern for the micro-controller.

### LCD Driver Output and Bias Circuit

The output number of the micro-controller LCD driver can be  $20\times3$  or  $19\times4$  by options (ie., 1/3 duty or 1/4 duty). The bias type of LCD driver is "R" type, no external capacitor is required. The LCD can be optioned as "LCD on at HALT" or "LCD off at HALT" which are dependent on options.

The SEG7~SEG18 also can be optioned as logical outputs. Each group of SEG7~SEG10, SEG11~SEG14 and SEG15~SEG18 can be optioned individually. Once an LCD segment is optioned as a logical output, the contents of bit 0 of the related segment address in LCD RAM will appear on the segment.

Memory	Segment Output
Bit 0=0	VSS
Bit 0=1	VDD

LCD Bias Block Diagram and Application Circuit

#### A/D Converter

The 8 channels and 8-bit resolution (7-bit accuracy) A/D converter are implemented in this microcontroller. The reference voltage is AVDD. The AVDD pin must be connected to VDD externally. Conversion accuracy may therefore be degraded by voltage drops and noise in the event of heavily loaded or badly coupled power supply lines. The A/D converter contains 3 special registers which are; ADR (21H), ADCR (22H) and ACSR (23H). The ADR is A/D result register. After the A/D conversion is completed, the ADR should be read to get the conversion result data. The ADCR is an A/D converter control register, which defines the A/D channel number, analog channel select, start A/D conversion control bit and the end of A/D conversion flag. If the users want to start an A/D conversion, after select the converted analog channel, and then give START bit a positive pulse  $(0 \rightarrow 1 \rightarrow 0)$ . At the end of A/D conversion, the EOCB bit is cleared and an A/D converter interrupt occurs(if the A/D converter interrupt is enabled). The ACSR is an A/D clock setting register, which is used to select the A/D clock source.

The A/D converter control register is used to control the A/D converter. The bit2~bit0 of the ADCR are used to select an analog input channel. There are a total of 8

channels to select. The bit5~bit3 of the ADCR are used to set PB configurations. PB can be an analog input or as digital I/O line decided by these 3 bits. Once a PB line is selected as an analog input, the I/O functions and pull-high resistor of this I/O line are disabled. The EOCB bit (bit 6 of the ADCR) is end of A/D conversion flag. Check this bit to know when A/D conversion is completed. The START bit of the ADCR is used to begin the conversion of A/D converter. Give START bit a falling edge that means the A/D conversion has started. The A/D converter remains in reset state while the START stays at "1". In order to ensure the A/D conversion is completed, the START should stay at "0" until the EOCB is cleared to "0" (end of A/D conversion).

The bit 7 of the ACSR is used for testing purpose only. It can not be used for the users. The bit1 and bit0 of the ACSR are used to select A/D clock sources.

When the A/D conversion is completed, the A/D interrupt request flag is set. The bit is set to "1" when the START bit is set to "1".

Register	Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0

EOCB	6	End of A/D conversion flag (0: end of A/D conversion)
START	7	<ul> <li>A/D conversion sequence (START=010)</li> <li>0: Initial value after chip RESET</li> <li>0→1: Initial next A/D conversion.</li> <li>1: reset A/D converter and set EOCB to "1"</li> <li>1→0: Starts the A/D conversion.</li> <li>0: Normal state for A/D</li> </ul>

Note: It is recommended that START is "0" and PCR2~PCR0 is "000" before MCU entering HALT mode. HALT will not standby the A/D converter automatically.

## ACSR Register

Label (ACSR)	Bits	Functions
ADCS0 ADCS1	0 1	ADCS1, ADCS0: Selects the A/D converter clock source 0,0: f <sub>SYS</sub> /2 0,1: f <sub>SYS</sub> /8 1,0: f <sub>SYS</sub> /32 1,1: Cannot be used
CMPC	2	Comparator control (*) 0: Disable 1: Enable
	3~6	Unused bit, read as "0"
TEST	7	For test mode used only 0: Normal mode 1: TEST only, cannot be used

Note: "\*" This bit is 0 during reset.

The following two programming examples illustrate how to setup and implement an A/D conversion. In the first example, the method of polling the EOCB bit in the ADCR register is used to detect when the conversion cycle is complete, whereas in the second example, the A/D interrupt is used to determine when the conversion is complete.

#### Example: using EOCB Polling Method to detect end of conversion

Example: using EOCB Polling Met	and to detect end of conversion
clr INTC0.3	; disable A/D interrupt in interrupt control register
mov a,00100000B	
mov ADCR,a	; setup ADCR register to configure Port PB0~PB3 as A/D inputs and select ; AN0 to be connected to the A/D converter
mov a,00000001B	
mov ACSR,a	; setup the ACSR register to select f <sub>SYS</sub> /8 as the A/D clock
	,
Start_conversion:	
clr ADCR.7	
set ADCR.7	; reset A/D
clr ADCR.7	; start A/D
Polling_EOC:	
sz ADCR.6	; poll the ADCR register EOCB bit to detect end of A/D conversion
jmp polling_EOC	; continue polling
mov a,ADR	; read conversion result from the high byte ADR register
mov adr_buffer,a	; save result to user defined register
imp start, conversion	· start payt A/D conversion
jmp start_conversion	; start next A/D conversion
Example: using Interrupt method t	o detect end of conversion
set INTC0.0	; interrupt global enable
set INTC0.3	; enable A/D interrupt in interrupt control register
	, enable A/D interrupt in interrupt control register
mov a,00100000B	actus ADCP register to configure Port PP0-DP2 on A/D inputs and colori
mov ADCR,a	; setup ADCR register to configure Port PB0~PB3 as A/D inputs and select ; AN0 to be connected to the A/D converter
mov a,00000001B	,
mov ACSR,a	; setup the ACSR register to select f <sub>SYS</sub> /8 as the A/D clock
	,
start_conversion:	
clr ADCR.7	
set ADCR.7	; reset A/D
clr ADCR.7	; start A/D
:	
; interrupt service routine	
EOC service routine:	
mov a_buffer,a	; save ACC to user defined register
mov a_builei,a	; read conversion result from the high byte ADR register
mov adr_buffer,a	; save result to user defined register
mov adi_bunei,a	, save result to user defined register
clr ADCR.7	
set ADCR.7	; reset A/D
clr ADCR.7	; start A/D
mov a,a_buffer	; restore ACC from temporary storage
reti	

Note: A/D clock must be fsys/2, fsys/8 or fsys/32

A/D Conversion Timing

#### PWM

The micro-controller provides 4 channels (6+2) bits PWM outputs shared with PD0~PD3. The PWM channels has their data register. The PWMs uses a PWM counter whose stages are 8 (stage 1~stage 8:  $f_{SYS}/2^1 \sim f_{SYS}/2^8$ ). The frequency source of the PWM counter comes from  $f_{SYS}$ . The PWM register is an eight bits register. The waveforms of PWM outputs are as shown. Once the PDi (i=0~3) is selected as the PWMi output

and the output function of PDi is enabled, writing "1" to PDi data register will enable the PWMi output function. Otherwise the PDi will stay at "0". The PWM modulation frequency, PWM cycle frequency and PWM cycle duty are summarized in the following table.

PWMi Modulation	PWMi Cycle	PWMi Cycle
Frequency	Frequency	Duty
f <sub>SYS</sub> /64	f <sub>SYS</sub> /256	[PWM]/256

PWM Mode

### Options

The following table shows all kinds of options in the microcontroller. All of the options must be defined to ensure proper system function.

No.	Options
1	PA wake-up enable or disable (1/0) options
2	WDT/LCD/RTC/Time Base Clock Source (f <sub>S</sub> ): RTCOSC(32768Hz crystal), T1D or WDTOSC (*1)
3	CLR WDT instructions: 1/2
4	WDT enable or disable
5	PA pull-high enable or disable (1 option : 4 bits (0~3/4~7))
6	PB pull-high enable or disable (1 option : 4 bits (0~3/4~7))
7	PC pull-high enable or disable (1 option : 4 bits (0~3/4~7))
8	PD pull-high enable or disable (1 option : 4 bits (0~3/4~7))
9	INT0 or INT1 trigger edge: disable; high to low; low to high; low to high or high to low.
10	COM3 or SEG19 (1/4 or 1/3 duty)
11	LCD on/off at halt mode
12	enable or disable Comparator
13	enable or disable PWMi function for PDi (bit optional)
14	$f_S/2^{12} \sim f_S/2^{15}$ : Time base period
15	SEG7~SEG18 logical or LCD output (1 option: 4 bits (SEG7~SEG10/SEG11~SEG14/SEG15~SEG18))
16	System oscillators: external RC/ external crystal
17	enable or disable RTCOSC(32.768kHz crystal) or WDTOSC at HALT mode
18	LCD bias current: Low/Middle/High driving current
19	LCD driver clock selection. There are seven types of frequency signals for the LCD driver circuits: $f_S/2^2 \sim f_S/2^8$ , " $f_S$ " stands for the clock source selection by options.

Note: "\*1" T1D is stopped at HALT; RTCOSC(32.768kHz crystal) and WDT OSC are stopped or non-stopped at HALT decided by option(18).

### **Application Circuits**

The following table shows the C1, C2 and R1 value according different crystal values.

Crystal or Resonator	C1, C2	R1
4MHz Crystal	0pF	10kΩ
4MHz Resonator (3 pin)	0pF	12kΩ
4MHz Resonator (2 pin)	10pF	12kΩ
3.58MHz Crystal	0pF	10kΩ
3.58MHz Resonator (2 pin)	25pF	10kΩ
2MHz Crystal & Resonator (2 pin)	25pF	10kΩ
1MHz Crystal	35pF	27kΩ
480kHz Resonator	300pF	9.1kΩ
455kHz Resonator	300pF	10kΩ
429kHz Resonator	300pF	10kΩ

Note: The resistance and capacitance for reset circuit should be designed in such a way as to ensure that the VDD is stable and remains within a valid operating voltage range before bringing RES to high.

"\*" Make the length of the wiring, which is connected to the  $\overline{\text{RES}}$  pin as short as possible, to avoid noise interference.

### Instruction Set Summary

Mnemonic	Description	Instruction Cycle	Flag Affected
Arithmetic	1	1	
ADD A,[m] ADDM A,[m] ADD A,x ADC A,[m] ADCM A,[m] SUB A,x SUB A,[m] SUBM A,[m]	Add data memory to ACC Add ACC to data memory Add immediate data to ACC Add data memory to ACC with carry Add ACC to data memory with carry Subtract immediate data from ACC Subtract data memory from ACC Subtract data memory from ACC	1 1 <sup>(1)</sup> 1 1 <sup>(1)</sup> 1 1 1 <sup>(1)</sup>	Z,C,AC,OV Z,C,AC,OV Z,C,AC,OV Z,C,AC,OV Z,C,AC,OV Z,C,AC,OV Z,C,AC,OV Z,C,AC,OV

Table Read			
TABRDC [m]	Read ROM code (current page) to data memory and TBLH	2(1)	None
TABRDL [m]	Read ROM code (last page) to data memory and TBLH	2 <sup>(1)</sup>	None
Miscellaneous	5		
NOP	No operation	1	None
CLR [m]	Clear data memory	1 <sup>(1)</sup>	None
SET [m]	Set data memory	1 <sup>(1)</sup>	None
CLR WDT	Clear Watchdog Timer	1	TO,PDF
CLR WDT1	Pre-clear Watchdog Timer	1	TO <sup>(4)</sup> ,PDF <sup>(4)</sup>
CLR WDT2	Pre-clear Watchdog Timer	1	TO <sup>(4)</sup> ,PDF <sup>(4)</sup>
SWAP [m]	Swap nibbles of data memory	1 <sup>(1)</sup>	None
SWAPA [m]	Swap nibbles of data memory with result in ACC	1	None
HALT	Enter power down mode	1	TO,PDF

Note: x: Immediate data

- m: Data memory address
- A: Accumulator

i: 0~7 number of bits

addr: Program memory address

- $\sqrt{}$ : Flag is affected
- -: Flag is not affected
- <sup>(1)</sup>: If a loading to the PCL register occurs, the execution cycle of instructions will be delayed for one more cycle (four system clocks).
- <sup>(2)</sup>: If a skipping to the next instruction occurs, the execution cycle of instructions will be delayed for one more cycle (four system clocks). Otherwise the original instruction cycle is unchanged.
- $^{(3)}\!\!:{}^{(1)}$  and  $^{(2)}\!\!$
- <sup>(4)</sup>: The flags may be affected by the execution status. If the Watchdog Timer is cleared by executing the CLR WDT1 or CLR WDT2 instruction, the TO and PDF are cleared. Otherwise the TO and PDF flags remain unchanged.

Operation		- [m].(i+1);	[m] i hit i c			
	ACC.7 ←		[iii].i.bit i t	of the data	i memory (	i=0~6)
Affected flag(s)	ACC.7 ←		[iii].i.bit i t	of the data	n memory (	i=0~6)
Affected flag(s)	ACC.7 ←		OV	of the data	a memory ( AC	i=0~6) C
Affected flag(s)	[	[m].0				
Affected flag(s) RRC [m]		[m].0 PDF		Z		
	TO — Rotate da The conte	[m].0 PDF — ta memor	OV — y right throw specified	Z — ugh carry data mem		C — ue carry fl
<b>RRC [m]</b> Description Operation	TO — Rotate da The conte right. Bit (	[m].0 PDF ta memory ents of the preplaces n].(i+1); [m	OV —	Z ugh carry data mem it; the orig	AC —	C — ne carry fl flag is rot
RRC [m] Description	TO Rotate da The conter right. Bit C [m].i $\leftarrow$ [m [m].7 $\leftarrow$ C C $\leftarrow$ [m].C	[m].0 PDF ta memory ents of the preplaces n].(i+1); [m c)	OV 	Z ugh carry data mem bit; the orig ne data me	AC — hory and th ginal carry emory (i=0	C — ee carry fl flag is rot ~6)
RRC [m] Description Operation	TO Rotate da The conte right. Bit ( [m].i $\leftarrow$ [m [m].7 $\leftarrow$ C	[m].0 PDF ta memory ents of the preplaces n].(i+1); [m	OV —	Z ugh carry data mem it; the orig	AC — hory and th	C — ne carry fl flag is rot

	Rotate right through carry and place result in the accumulator							
Description	Data of the specified data memory and the carry flag are rotated 1 bit right. Bit 0 replace the carry bit and the original carry flag is rotated into the bit 7 position. The rotated result is stored in the accumulator. The contents of the data memory remain unchanged.							
Operation	ACC.i $\leftarrow$ [m].(i+1); [m].i:bit i of the data memory (i=0~6) ACC.7 $\leftarrow$ C C $\leftarrow$ [m].0
