

Features

- Processed with BCDMOS on SOI (Silicon On Insulator)
- DC to 10MHz analog signal frequency
- Surface mount package available
- Low quiescent power dissipation ($< 1\mu A$ typical)
- Output on-resistance typically 20Ω
- TTL I/O's for 3.3V interface
- Adjustable high voltage supplies

Applications

- Ultrasound imaging
- Printers
- Industrial controls and measurement

Description

The CPC7220 is a low charge injection 8-channel high-voltage analog switch integrated circuit (IC) for use in applications requiring high voltage switching. Control of the high voltage switching is via low voltage TTL logic level compatible inputs for direct connectivity to the system controller.

Switch manipulation is managed by an 8-bit serial to parallel shift register whose outputs are buffered and stored by an 8-bit transparent latch. Level shifters buffer the latch outputs and operate the high voltage switches.

Because the CPC7220 is capable of switching high load voltages and has a flexible load voltage range, e.g. $V_{PP}/V_{NN} : +40V/-160V$ or $+100V/-100V$, it is well suited for many medical and industrial applications such as medical ultrasound imaging, printers, and industrial measurement equipment.

Construction of the high voltage switches using Clare's reliable BCDMOS process technology on SOI (Silicon On Insulator) allow the switches to be organized as solid state switches with direct gate drive.

Absolute Maximum Ratings (@ 25° C)

Parameter	Ratings	Units
V_{DD} logic power supply voltage	-0.5 to +6	V
$V_{PP} - V_{NN}$ supply voltage	220	V
V_{PP} positive high voltage supply	-0.5 to $V_{NN} + 200$	V
V_{NN} negative high voltage supply	+0.5 to $V_{PP} - 200$	V
Logic input voltages	-0.5 to $V_{DD} + 0.3$	V
Analog signal range	V_{NN} to V_{PP}	-
Peak analog signal current/channel	1	A
Power dissipation	1.2	W
Storage Temperature	-60 to +150	°C

Absolute Maximum Ratings are stress ratings. Stresses in excess of these ratings can cause permanent damage to the device. Functional operation of the device at conditions beyond those indicated in the operational sections of this data sheet is not implied.

Operating Conditions

Parameter	Symbol	Value
Logic power supply voltage ^{1,3}	V_{DD}	4.5V to 6V
Positive high voltage supply ^{1,3}	V_{PP}	40V to $V_{NN} + 200V$
Negative high voltage supply ^{1,3}	V_{NN}	-40V to -160V
Analog signal voltage peak to peak ²	V_{SIG}	$V_{NN} + 10V$ to $V_{PP} - 10V$
Operating temperature	T_A	0°C to 70°C

NOTES:

¹ Power up/down sequence is arbitrary except GND must be powered-up first and powered-down last.

² V_{SIG} must be $V_{NN} \leq V_{SIG} \leq V_{PP}$ or floating during power up/down transition.

³ Rise and fall times of power supplies V_{DD} , V_{PP} and V_{NN} should not be less than 1msec.

CPC7220 Description

The CPC7220 takes a serial stream of input data along with a synchronous clock signal. As the clock transits from low to high, the data at the input of each shift register is shifted through from SR(n) to SR(n+1). A high data bit, a "1," represents an ON switch; a low data bit, a "0," represents an OFF switch. Data is input and shifted through the internal shift register until all eight shift register positions, SR0 through SR7, are in the desired state.

D_{IN}: The data-in line presents data bits to the CPC7220 to be shifted through the internal shift register.

CLK: The clock signal's rising edge is associated only with shifting data into and through the shift register.

CL: The clear line overrides all other inputs. When CL is high, the shift register is cleared to all 0s and all latches are set low, which causes all output switches to be turned OFF immediately. When CL is low, all output switches remain in whatever state they are in, ON or OFF, in response to CLK, latch inputs, and the $\overline{LE}$ signal.

$\overline{LE}$: latch enable controls the state of the latches and thus the state of the eight switches. If $\overline{LE}$ is high, then the latches do not change states, but retain their most recent status: either ON or OFF. With $\overline{LE}$ high, input data and CLK have no effect on the state of the output switches. If $\overline{LE}$ is low, then all latch outputs and their switch states follow the inputs from the shift register. $\overline{LE}$ is overridden by CL: no matter what state $\overline{LE}$ is in, CL clears the latches. See table on page 10.

D_{OUT}: The data-out pin is the output of SR7. After eight clock pulses, the first bit of eight input data bits is shifted to SR7 and appears on D_{OUT}.

SW0 - SW7: The CPC7220 provides eight high-voltage SPST output switches with a typical on-resistance of 20Ω. The two connections of each switch are not polarity-sensitive.

V_{PP} and V_{NN}: Voltage inputs to the level shifters for each switch channel that translate the voltage level of the latch output signals to an appropriate level for the voltages being switched.

The high-voltage output switches are turned on and off in response to the data sent into the latches from the shift register: data 0 turns a switch OFF, data 1

turns a switch ON.

Two or more CPC7220 devices can be cascaded to form an n-switch arrangement. The D_{OUT} pin of the first is connected to the D_{IN} pin of the next in the series. All devices are connected to the same clock (CLK) signal. $\overline{LE}$ of all devices would normally be connected, as would CL, but this is not necessary.

The first data bit applied to D_{IN} of the CPC7220, whether it's a single device or several cascaded devices, ripples through to the last switch output in line after the application of a full clocking sequence of 8 clock pulses per CPC7220. Setting the serial I/O device to output the most significant bit (MSB) first, results in the MSB appearing on SW7 of the last device in line after a full clocking sequence.

Notes:

1. The eight switches operate independently.
2. Serial data is clocked in on the L→H transition CLK.
3. The switches go to a state retaining their present condition at the rising edge of $\overline{LE}$. When $\overline{LE}$ is low the shift register data flows through the latch.
4. D_{OUT} is high when switch 7 is on.
5. Shift register clocking has no effect on the switch states if $\overline{LE}$ is H.
6. The clear input overrides all other inputs.

Manufacturing Information

Soldering

For proper assembly, the component must be processed in accordance with the current revision of IPC/JEDEC standard J-STD-020. Failure to follow the recommended guidelines may cause permanent damage to the device resulting in impaired performance and/or a reduced lifetime expectancy.

Washing

Clare does not recommend ultrasonic cleaning or the use of chlorinated solvents.
